TABLE 4. OLIGOMERS WITH ALIPHATIC SIDE CHAINS WHICH IN ADDITION CONTAIN HETEROATOMS

4.1. OLIGOMERIC ACRYLIC DERIVATIVES

4.1.1. OLIGO(ACRYLIC ACIDS)

4.1.1.1. $H[CH_2CH(COOH)]_nCH_3$

n	Mol. wt.	Configuration	m.p. (°C)	b.p. (°C/mbar)	Refs.
1	88.1		−46	153/1012	
2	160.2	Isotactic (meso)	128		1–3,11
		Syndiotactic (racemic)	141		1–3,11
3	232.2	Isotactic (meso)	167.5–170.0		3,78
		Heterotactic (racemic)	160.0–163.0		3,78
		Syndiotactic (meso)	153.5–154.5		3,78

4.1.1.2. $(CH_3)_2C(COOH)-[CH_2CH(COOH)]_n-C(COOH)(CH_3)_2$

n	Mol. wt.	m.p. (°C)	Refs.
1	246.3	30–35	4
2	318.3	70–80[a]	4
3	390.4	181–183	4
4	462.5	80–82	5

[a] *p*-Nitrobenzyl ester.

4.1.2. OLIGO (ACRYLATES)

4.1.2.1. $H[CH_2CH(COOH)]_nCH_3$

n	Mol. wt.	Configuration	b.p. (°C/mbar)	n_D/°C	Refs.
1	102.1		91.5/990	1.3838/20	6
2	188.2	Isotactic (meso)	64/0.9	1.4258	3,6,101
		Syndiotactic (racemic)	NMR		3
3	274.3	Isotactic (meso)	163/15	1.4440	3,6,78
		Heterotactic (racemic)	160/15	1.4420	3,6,78
		Syndiotactic (meso)	156/15	1.4407	3,6,78

4.1.2.2. Anionic Oligomers $RO[CH_2CH(COOR)]_nH$

R	*n*	Mol. wt.	b.p. (°C/mbar)	n_D^{25}	Refs.
CH_3	1	118.1	55–56/27		7
CH_3	2	204.2	90/1	1.433	7
C_2H_5	1	146.2	75–77/27		7,42,56
C_2H_5	2	246.3	82/0.15	1.446	7,42,56,62

4.1.2.3. Unsaturated Oligomers

Oligomers	R	*n*	Mol. wt.	b.p. (°C/mbar)	n_D^{25}	Refs.
Dialkyl-Δ^2-dihydromuconate (*trans*)	CH_3	2	172.2	86–88/1.3	1.4497	42,44,58,60,61,63
ROOC–CH=CH–CH_2CH_2COOR	C_2H_5	2	200.2	80–84/1.3		58
Dialkyl-Δ^3-dihydromuconate	CH_3	2	172.2	74–75/1.3		42,58,60,63
ROOC–CH_2–CH=CH–CH_2COOR	C_2H_5	2	200.2	107–108/1.3		58,63
Dialkyl-α-methyleneglutarate oligomers	CH_3	1	172.2	59/0.3		7,8,42,44,62

4.1.2.3. cont'd

Oligomers	R	n	Mol. wt.	b.p. (°C/mbar)	n_D^{25}	Refs.
CH_2=C(COOR)–[CH_2CH(COOR)]$_n$H		2	258.2	120/0.9		8
		3	344.3	166–168/0.4		8
		4	430.4	180/0.03		8
	C_2H_5	1	200.2	52–53/0.2	1.0392	42,52,56,62

4.1.3. ANIONIC OLIGOMERS OF ACRYLAMIDE CH_2=CHCO–[NHCH$_2$CH$_2$CO]$_n$NH$_2$

n	Mol. wt.	m.p. (°C)	Refs.
1	142.2	149–150	110–112
2	213.2	179–181	112

4.1.4. OLIGO(ACRYLONITRILES)

4.1.4.1. H[CH$_2$CH(CN)]$_n$H

n	Mol. wt.	b.p. (°C/mbar)	n_D/°C	Refs.
1	55.1	97.1/1013	1.3689/15	
2	108.1	116–118/6.5	1.4320/25	9,45
3	161.2	195–196/3.5	1.4609/20	9,10,45

4.1.4.2. H[CH$_2$CH(CN)]$_n$CH$_3$

n^a	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	d_4^{64}/°C (g/cm^3)	n_D/°C	Refs.
1	69.1	−71.5	107–108/1013	0.773	1.3720/20	37
2	122.2	8.8[b]	106/3	0.9051	1.4191/60	10,11,38,54,80
		55[c]	94/3	0.8940	1.4155/60	10,11,38,54,80
3	175.2	37–39[b]				10,38,53
		53–54[d]				10,53
		80–81[e]				10,53
4	228.3	130–132[f]				10
		158				10

[a] n = 2–5 (diastereomers): ^{13}C-NMR, Ref. 35.
[b] Isotactic (meso).
[c] Syndiotactic (racemic).
[d] Heterotactic (racemic).
[e] Syndiotactic (meso).
[f] Two stereoisomers.

4.1.4.3. H[CH(CN)CH$_2$]$_n$CH$_2$CN

n	Mol. wt.	b.p. (°C/mbar)	n_D/°C	Refs.
1	94.1	287.4/1013	1.4347/20	
2	147.2	85/0.01	1.4644/25	9,12
3	200.2	95/0.01		9,12

4.1.4.4. 1,2-Dicyanocyclobutanes

n	Configuration	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{25}	Refs.
1	*cis/trans*	106.1				13,42,43,66,81
	cis		67–67.5	190/20	1.4628	13,14,79
	trans		30.5/31.5	160/20		13,14,79

4.1.4.5. Unsaturated Oligomers

Oligomers[a]	n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{25}	Refs.
2,3-Dihydromuconitrile $NCCH_2CH{=}CHCH_2CN$	2	106.1	76			14,15,82
1,4-Dicyano-1-butene $CN{-}CH{=}CH{-}CH_2CH_2CN$	2	106.1				42,46,49,67
cis			−19 to −17	99.5–102.5/0.5	1.4677	49,50,83
trans			−13 to −12	84.5–86.5/0.5	1.4646	49,50
2-Methyleneglutaronitrile $CH_2{=}C(CN){-}CH_2CH_2CN$ (*cis/trans*)	2	106.1	−9.6	65/0.13	1.4550	42,44–48,52
2,4,6-Tricyano-1-hexene $CH_2{=}C(CN){-}CH_2CH(CN){-}CH_2CH_2CN$	3	159.2		152–164/2.5	1.4762	42,45
1,1,4,4-Tetracyanoethyl-1,4-dicyano-2-butene $(NCCH_2CH_2)_2C(CN){-}CH{=}CH{-}C(CN)(CH_2CH_2CN)_2$	6	318.4	240			14,45,46
1,4-Dicyano-1,3-butadiene NC–CH=CH–CH=CH–CH	2	104.1				42,51
cis,cis			128–129			83
trans,trans			159–161			97

4.2. OLIGOMERIC METHACRYLIC DERIVATIVES

4.2.1. OLIGO(METHACRYLIC ACIDS)

4.2.1.1. $H[CH_2C(CH_3)(COOH)]_n{-}C(COOH)(CH_3)_2$

n	Mol. wt.	m.p. (°C)	Refs.
2	260.3	Oil	19
3	346.4	45–48	18,19
4	432.5	56–59	19

4.2.1.2. Anionic Oligo(methacrylic acids)

n	Mol. wt.	m.p. (°C)	Refs.
$CH_3O{-}[CH_2C(CH_3)(COOH)]_nH$			
2	204.2	82	17
3	290.3	160	17

4.2.2. OLIGO(METHACRYLATES)

4.2.2.1. Anionic Oligo(methacrylates) $RO{-}[CH_2C(CH_3)(COOOR)]_nH$

R	R′	n	Mol. wt.	b.p. (°C/mbar)	d^{20}/(g/cm³) °C	n_D^{20}	Refs.
CH_3O	CH_3O	1	132.2	147/1013	0.7949	1.4053	17,36,41,73
		2	232.3	241/1013	1.0540	1.4378	17,36,41
		3	332.4	116/0.1	1.1045	1.4567	17,36,41
		4	432.5	190/0.1	1.12	1.4681	17
		6	632.8		1.565		17
			n = 2–10: GPC Ref. 36				
$n{-}C_4H_9O$	$n{-}C_4H_9O$	1	216.3	59–61/0.13	0.8970	1.4213	74
		2	358.5	128–130/0.13	0.9436	1.4400	74
		3	500.7	186–90/0.13	0.9736	1.4508	74
		4	642.9	246–250/0.4	0.9909	1.4574	74

Isotactic and syndiotactic oligomers, $(CH_3)_3C{-}[CH_2C(CH_3)COOCH_3]_n{-}H$, n = 2–100 (mol. wt. 158.2–10070.0): HPLC, GPC, SFC; DSC (T_g, T_m), X-ray (n = 2–5), NMR, MS; Refs. 114–124.
Reviews: Refs. 114,115.
Properties of specific oligomers: n (isotactic and syndiotactic, resp.) = 2–8,13,14,16,19,21,22–25,27–29,31,36,41,44,45,50,58,80,100.
m.p. (°C), (isotactic oligomers): n = 28: 98.5, n = 31: 104.5, n = 36: 109.6, n = 41: 117.3, n = 44: 124.3; Ref. 116.

4.2.2.2. Unsaturated Oligomers[a] $CH_2{=}C(COOCH_3){-}[CH_2{-}X{-}(COOCH_3)]_n{-}CH_3$

X	*n*	Mol. wt.	b.p. (°C/mbar)	n_D^{25}	Refs.

4.3.2. OLIGO(CROTONONITRILES)

Oligomers	*n*	Mol. wt.	b.p. (°C/mbar)	n_D^{25}	Refs.
1,3-Dicyano-2-methyl-3-pentene (*cis/trans*) $CH_3CH{=}C(CN){-}CH(CH_3)CH_2CN$	2	134.2	81–83/0.3	1.4730	42,52,55–57
1,3,5-Tricyano-2,4,6-trimethylcyclohexane ┌[CH(CN)–CH(CH₃)]₃┐	3	201.3	152–155/0.3	1.4950	42,57
1,3,5-Tricyano-2,4-dimethyl-5-heptene $CH_3CH{=}C(CN){-}CH(CH_3)CH(CN){-}CH(CH_3)CH_2CN$	3		150–160/0.13		42,52

4.4. OLIGO(VINYL) DERIVATIVES

4.4.1. OLIGO(VINYL ALCOHOLS) AND OLIGO(VINYL ACETATES) $H[CH_2CHOR]_nCH_3$

R	*n*	Configuration	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
H	2	Isotactic (meso)	104.1		73/4	1.4327	80,86,87
		Syndiotactic (racemic)		48–49	74/4	1.4378	80,86,87
	3	Isotactic (meso)	148.2	67	120/1.3		84,85
		Heterotactic (racemic)			120/1.3		84,85
		Syndiotactic (meso)		87.5–88			84,85
$COCH_3$	2	Isotactic (meso)	188.2		20/1013	1.4172	86,88,97
		Syndiotactic (racemic)			201/1013	1.4142	86,88,97
		Mixture			103–107/27	1.4170	96
	3	Isotactic	274.3		116–117.5/0.7	1.4342	84,88
		Heterotactic		21–22	115–116/0.7	1.4319	84
		Syndiotactic		32.5–33.5	112–114/0.5	1.4297	84,88
		Mixture			120–122/0.7	1.4320	84,96

4.4.2. OLIGO(VINYL CHLORIDES) $H[CH_2CHCL]_nCH_3$ [a]

n	Configuration	Mol. wt.	b.p. (°C/mbar)	n_D^{20}	Refs.
2[b]	Isotactic (meso)	141.0	40/16	1.4409	80,90–95,97
	Syndiotactic (racemic)		36/16	1.4390	80,90–95,97
	Mixture		140–141/1013	1.4409	95
3[b]	Isotactic	203.5	102.5/20	1.4722	89,94,95
	Heterotactic		103.5/20	1.4704	89,94,95
	Syndiotactic		104.5/20	1.4686	89,94,95
	Mixture		102.5–104.5	1.4699	89

[a] Oligomers $(CH_3)_3C{-}[CH_2CHCl]_n{-}H$, $n = 1,2,3$ (threo-; erythro-), 4 (ribo-; xylo-; arabino-; lyxo-): HPLC, ^{13}C-NMR, Ref. 39.
[b] 2,4-Dibromopentanes and 2,4,6-tribromoheptanes: Kerr Effekt, Ref. 98.

4.4.3. OLIGO(VINYL ALDEHYDES) AND OLIGO(VINYL KETONES)

Monomer	Oligomers	*n*	Mol. wt.	m.p. (°C)	b.p. (C/mbar)	Refs.
Acrolein $CH_2{=}CHCHO$	2-Formyl-2,3-dihydropyran 	2	112.1		145–148/1013	22–25
	3-Formyl-5,6-dihydropyran 	2	112.1		77–78/16	26,27
α-Methylacrolein $CH_2{=}C(CH_3)CHO$	2-Formyl-2,5-dimethyl-2,3-dihydropyran 	2	140.2	−75	166/1000	24,28
α-Ethylacrolein $CH_2{=}C(CH_2H_5)CHO$	2-Formyl-2,5-diethyl-2,3-dihydropyran 	2	168.2		195/1013	24

4.4.3. *cont'd*

Monomer	Oligomers	n	Mol. wt.	m.p. (°C)	b.p. (C/mbar)	Refs.
Methyl vinyl ketone $CH_2=CH-CO-CH_3$	2-Methyl-6-acetyl-5,6-dihydropyran 	2	128.2		68/17	29
	3-Methylene-2,6-heptanedione $CH_3COC(=CH_2)CH_2CH_2COCH_3$	2	140.2	5–7	91–92/7	46

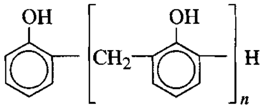
TABLE 20. PHENOL-FORMALDEHYDE AND RELATED OLIGOMERS

20.1. LINEAR PHENOL-FORMALDEHYDE OLIGOMERS

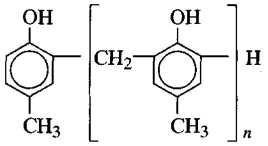
20.1.1. PHENOL-FORMALDEHYDE OLIGOMERS



n	Mol. wt.	m.p. (°C)	Refs.
1	200.2	119–120	1–4
2	306.4	158–159	2–6
3	412.5	161–162	3,4
4	518.6	148–150	4,7
5	624.7	203–204	4
6	730.8	213–214	4

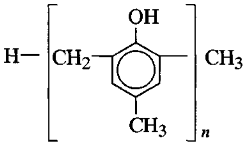
20.1.2. *p*-CRESOL-FORMALDEHYDE OLIGOMERS

20.1.2.1.



n	Mol. wt.	m.p. (°C)	Refs.
	228.3	126	8–10,56–58
2	348.4	214–215	8–11,56–58
3	468.6	173	8,9,56,57
4	588.7	130	12,56,57
5	708.9	215–217	12
6	829.1	225–230	12
7	949.2	167–170	12
8	1069.4	205–210	12
9	1189.5	175–180	12
11	1429.8	245	12

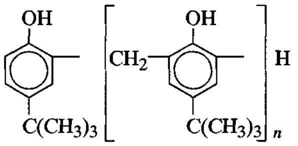
20.1.2.2.



n	Mol. wt.	m.p. (°C)	Refs.
1	136.1	70–72	61
2	256.3	148	11,13–16
3	376.5	183–184	11
4	496.7	204–205	11
5	616.9	152–154	61

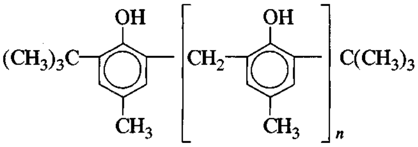
20.1.3. p-tert BUTYLPHENOL-FORMALDEHYDE OLIGOMERS

20.1.3.1.



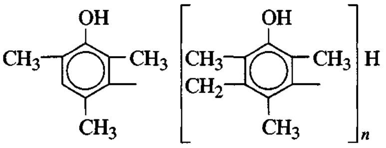
n	Mol. wt.	m.p. (°C)	Refs.
1	312.5	156	17,18,62
2	474.7	218–220	17,18,62
3	636.9	211	17,18,62
4	799.2	216–217	17,18,62
5	961.4	250	17,18,62
6	1123.6	249–250	17,18
7	1285.9	253–256	18
8	1448.1	224–226	17
10	1772.6	140	17

20.1.3.2.



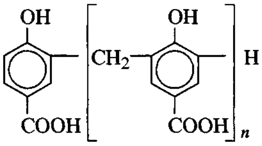
n	Mol. wt.	m.p. (°C)	Refs.
0	220.4	70–71	61
1	340.5	125–130	61
2	460.7	82–84	61
4	701.0	188–190	61

20.1.4. 2,4,6-MESITOL–FORMALDEHYDE OLIGOMERS



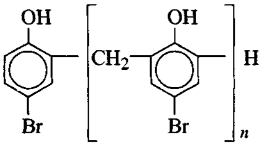
n	Mol. wt.	m.p. (°C)	Refs.
1	284.4	188	19
2	432.6	257	19

20.1.5. 4-CARBOXY-PHENOL–FORMALDEHYDE OLIGOMERS



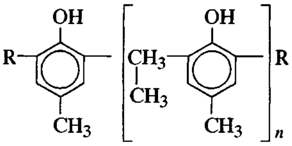
n	Mol. wt.	m.p. (°C)	Refs.
1	288.3	305–307	59
2	438.4	310	59

20.1.6. 4-BROMO-PHENOL–FORMALDEHYDE OLIGOMERS



n	Mol. wt.	m.p. (°C)	Refs.
1	358.1	183–184	1,60
2	543.1	237–238	60

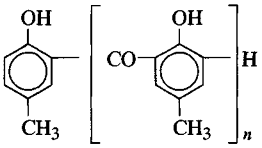
20.1.7. *p*-CRESOL–ACETALDEHYDE OLIGOMERS



R	n	Mol. wt.	m.p. (°C)	Refs.
H	1	241.3	141	20,21
H	2	373.5	214–215	21
CH_3	1	270.4	135–135.5	22
CH_3	2	404.6	154–155	63
CH_3	3	538.7	204–205	63

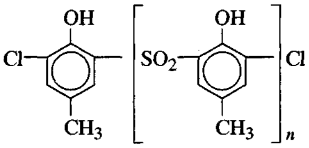
20.1.8. OLIGOMERS WITH CARBONYL AND SULFONYL BRIDGES

20.1.8.1.



n	Mol. wt.	m.p. (°C)	Refs.
1	242.3	106–107	23,24,56–58
2	376.4	122–123	24,56,57

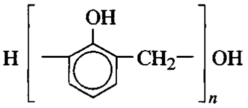
20.1.8.2.



n	Mol. wt.	m.p. (°C)	Refs.
1	347.2	179	25
2	517.4	238–240	25
3	687.6	246–252	25

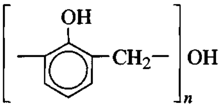
20.2. OLIGOMERIC PHENOL ALCOHOLS

20.2.1. OLIGOMERIC PHENOL ALCOHOLS



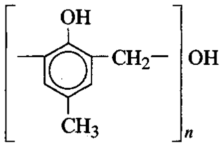
n	Mol. wt.	m.p. (°C)	Refs.
1	124.1	86–87	3,26
2	230.3	121.5–123	3,27,28

20.2.2. PHENOL DIALCOHOLS $HOCH_2$



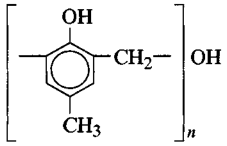
n	Mol. wt.	m.p. (°C)	Refs.
1	154.2	101	29–32
2	260.3	126–127	28

20.2.3. *p*-CRESOL MONOALCOHOLS H



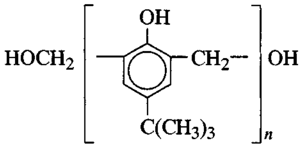
n	Mol. wt.	m.p. (°C)	Refs.
1	138.2	107	8,33,34
2	258.3	148	8,9,35
4	498.6		36

20.2.4. *p*-CRESOL DIALCOHOLS HOCH2



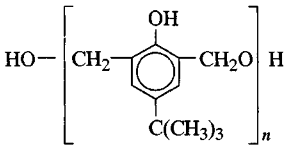
n	Mol. wt.	m.p. (°C)	Refs.
1	168.2	133–134	13,37
2	288.3	151.5	9,35,38,39
3	408.5	203	9,39,40

20.2.5. *p-tert* BUTYLPHENOL DIALCOHOLS



n	Mol. wt.	m.p. (°C)	Refs.
1	210.3	74–75	41
2	372.5	117–118	18

20.2.6. *o*-HYDROXYDIBENZYL ETHERS



n	Mol. wt.	m.p. (°C)	Refs.
2	318.4	85	42

20.3. CYCLIC PHENOL–FORMALDEHYDE OLIGOMERS

20.3.1.

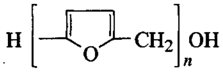
E. OLIGOMERS CONTAINING HETEROCYCLIC RINGS IN THE MAIN CHAIN

TABLE 22. HETEROCYCLIC OLIGOMERS

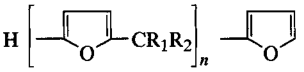
22.1. OLIGO(FURAN)DERIVATIVES

22.1.1. OLIGO(FURFURYL) ALCOHOLS



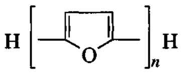
n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
1	98.1		171/1000	1.4868	10,11
2	178.2	− 2.5	141–143/12	1.5290	10–12,14
3	258.3	62–62.5	192.5–295/8		10–12,14

22.1.2. OLIGO(FURFURYL) FURANS



R_1	R_2	n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	d_4^{20} (g/cm³)	n_D^{20}	Refs.
H	H	1	148.2		78/16	1.102	1.5048	10,12,14–15,39
		2	228.2		141–146/11		1.5324	10,12
		3	308.3	74–75				10,12,14
		4	388.4	99–101				10,14
H	CH_3	1	162.2		91/28	1.073	1.4993	16,17
		2	256.3		114–116/0.13			17
		3	350.4		165–168/0.04			16,17
CH_3	CH_3	1	176.2	− 12	73–76/7–8	1.043	1.4966	17,18
		2	284.3	47.0/47.5	120–123/1.3			17,18
		3	392.5		163–167/1.3	1.030	1.5172	17,18
		4	500.6	Oil				17
		5	608.7	83–85				17
CH_3	C_2H_5	1	190.2		68–70/3	1.033	1.4970	18
		2	312.4		143–145/1.3	1.045	1.5094	19
		3	434.6		205–210/1.3	1.046	1.5173	19
C_2H_5	C_2H_5	1	204.3	−9 to −8	76–77/3	1.023	1.4978	20
		2	340.4		162–163/2	1.028	1.5089	20
		3	476.6		212–215/2	1.034	1.5199	20
		1	216.3	13–17	94–95/2			21
		2	364.5	86.8–87.6	200–205/2	1.018	1.5221	21

22.1.3. 2,5-OLIGO(FURYLENES)



n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	d_4^{20} (g/cm³)	n_D^{20}	Refs.
1	68.1	− 85.7	31.4/1013	0.9514/20	1.4214/20	
2	134.1		63–64/15		1.5601/22	39–41,42
3	200.2	62–63				32

22.1.4. FURANOPHANES 
R′	R″	n	Mol. wt.	m.p. (°C)	Refs.
H	CH_3	4	376.4	140–142	16,17,22
	r-2,c-7,c-12,c-17-			191.0–192.0	22
H	C_2H_5	4	432.5	83–88	22
	r-2,c-7,c-12,c-17-			152.0–153.0	22
CH_3	CH_3	4	432.5	243	18,23,24
CH_3	CH_3	5	540.7	Oil	17
		6	648.8	182	17,18,24
CH_3	C_2H_5	4	488.5	174	18,19,22,24
C_2H_5	C_2H_5	4	544.7	249–250	18,20,24
H		4	592.8	268–269	21,24

22.1.5. TETRAHYDROFURANOPHANES 
n	Mol. wt.	m.p. (°C)	Refs.
4	448.7	204–209	17,18,20,21,23
	r-(1S, 3S, 6R, 8S, 11R, 13R, 16S, 18R)-	218	25
	r-(1S, 3R, 6S, 8R, 11S, 13R, 16S, 18R)-	221	25
5	560.8	Oil	17
6	673.0	75–80	17

22.2. OLIGO(THIOPHENE) DERIVATIVES

22.2.1. OLIGO(2.5-THIENYLENES) 
n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
1	84.1	−38.4	84.2/1013	1.5289	
2	166.3	33–34	125/16		1,27,28,34,41,42,44,49
3	248.4	96–97			1,3,26,28,30–33,42,44,47,49
4	330.5	215–216			1,3,27–29,41,42,44,46,49
5	412.5	257–258			1,3,28,29,42,48
6	494.8	304–305			3,27,28,42,44,46
7	576.9	327–328			3,29,48
8	659.0	364			42,46

22.3. OLIGO(PYRROLE) DERIVATIVES

22.3.1. OLIGO(PYRROLE) DERIVATIVES

No.	Oligomers	R	n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	Refs.
1			2	214.3	105–106		21,43
2		CH_3	2	174.2	59	125–126/4	35
3			4	428.6	291		36,37
			4	588.8	272.0–272.5		21

22.3.2. OLIGO[2,5-(*N*-METHYL)PYRROLENES] 
n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	Refs.
1	81.1		114–115/99.6	
2	160.2	14–15	77–78/0.5	13,42
4	318.4	134		42
5	397.5	145		42
6	476.6	160		42
8	634.8	178–182		42
16	1267.6	240–256		42

22.4. OLIGO(PYRIDINE) DERIVATIVES

22.4.1. OLIGO(2,6-PYRIDYLENES) 
n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
1	79.1	−42	115.5/1013	1.5095	
2	156.2	70.1	273–275/1013		4,5
3	233.3	89–90	370/1013		2,4–6
4	310.4	219–220			5
5	387.5	265			5
6	464.5	350			5

22.4.2. OLIGO(3,5-PYRIDYLENES) H  H

n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
1	79.1	− 42	115.5	1.5095	
2	156.2	68	291–292/981		4,9
3	233.3	249–251			9

22.4.3. OLIGO(2,6-QUINOLYLENES) H  H

n	Mol. wt.	m.p. (°C)	b.p. (°C/mbar)	n_D^{20}	Refs.
1	129.2	− 15.6	238.1/1013	1.6268	
2	256.3	144			7,8
3	383.5	267–269			8
4	510.6	348–350			8

22.5. CYCLIC OLIGO(HETEROCYCLICS)

No.		Mol. wt.	m.p. (°C)	Refs.
1		188.2	189–190	38
2		220.3	194.5–196	38
3		264.2	233	42,45
4		328.5	255–256	42,45
5		492.7	420	42,45
6		328.5	300–301	42,45
7		528.7	410	45
8		312.3	355–360	45

A. INTRODUCTION

Where a range is given, there are available several observations which differ. In most cases the differences are thought to be real, arising from differences in the rubber rather than from errors of observation. Where a single value is given, it is either because no other observations are available or because there seems to be no significant disagreement among values within the errors of observation. Where values are not given, data have not been found. Where dashes are shown, either the physical measurement is impossible or the constant in question is not adequately defined under the given conditions. The values shown refer to specific vulcanizates cited in the corresponding references. Other vulcanizates may yield a broader range of values.

The values are expressed in the International System of Units (SI), the modern metric system, described in National Bureau of Standards Special Publication 330, 1981 edition, and in American Society for Testing and Materials Metric Practice Guide E380–85.

Values are given for constants at a temperature of 25°C (273.15 K) and a pressure of 1 normal atmosphere = 101.325 kPa.

A. CRYSTALLOGRAPHIC DATA AND CRYSTALLOGRAPHIC MODIFICATIONS[a]

Crystal system	Space group	Lattice constants (nm) *a*	*b*	*c*	α, β, or γ (deg.)	Number of chains per unit cell	Molecular conformation	Crystal density (g/cm^3)	Refs.
Orthorhombic stable form	Pnam-D_{2h}	0.7417	0.4945	0.2547		2	Planar Zigzag (2/1)	1.00	3–7
Monoclinic metastable form	C2/m-C_{2h}	0.809	f.a. = 0.253[b]	0.479	β = 107.9	2	Planar Zigzag (2/1)	0.998	4,8
Hexagonal high-pressure form		0.842	–	f.a.[c]			–	–	9–11

[a] Refs. 1,2.
[b] f.a. indicates fiber axis.
[c] Not determined.

Temperature Dependence of Crystallographic Data for Orthorhombic Poly(ethylene)[a]

Temp. (K)	Lattice constants (nm) *a*	*b*	*c*	Specific volume (cm^3/g)	Refs.
4[b]	0.712	0.485	0.2548	0.945	12
10	0.716	0.486	0.2534	0.947	13
77	0.718	0.488	0.2534	0.953	13
77	0.715	0.490	0.2547	0.959	14
90[b]	0.716	0.487	0.2546	0.953	12
195	0.727	0.491	0.2534	0.971	13
293[c]	0.740	0.495	0.2543	0.999	5
	(0.743)	(0.494)	(0.2543)	(1.003)	5
297	0.742	0.496	0.2534	1.001	13
297	0.740	0.493	0.2534	0.993	3
297	0.736	0.492	0.2534	0.985	15
303	0.741	0.494	0.2547	1.002	14

[a] Ref. 1. Data obtained by X-ray diffraction studies unless otherwise indicated.
[b] Data obtained by neutron diffraction.
[c] The data of nonoriented samples are given without parentheses and those of oriented samples are given with parentheses, both for high-density PE.

* Based on a table in the third edition, by R. P. Quirk and M. A. A. Alsamarraie, The Maurice Morton Institute of Polymer Science, University of Akron, Akron, Ohio.

B. MOLECULAR PARAMETERS AND SOLUTION PROPERTIES

Bond Angle and Bond Length

	Wide angle X-ray[a] (Refs. 3,4,16)	Neutron scattering (Ref. 12)	Temp. (K)
BOND ANGLE (in degrees)			
C–C–C	112.0	107.7	4
		108.1	90
H–C–H	107.0	109.0	4
		110.0	90
BOND LENGTH (nm)			
C–C	0.153	0.158	4
		0.157	90
C–H	0.107	0.106	4
		0.107	90

[a] Measurements taken at room temperature.

Dimensions of Linear Polyethylene Molecules[a]

Temperature (°C)	PEH Matrix $\overline{M}_w$ ($\times 10^3$)	$\overline{M}_w$ ($\times 10^3$)	PED[b] $\langle S^2\rangle_z^{1/2}$† (nm)	PED[b] $\langle S^2\rangle_w^{1/2}/\overline{M}_w^{1/2}$‡ [nm/(g/mole)$^{1/2}$]	State	Refs.
23 (296.2)[c]	78	60	13.3	0.046	Crystalline	17
150 (423.2)	100	140	21.5	0.046	Molten	17
150 (423.2)	80	10	4.38	0.044	Molten	18

[a] Effect of temperature and state, neutron scattering measurements.
[b] Deuterated polyethylene.
[c] Values in parentheses indicate temperature in kelvin.
† $\langle S^2\rangle_z^{1/2}$ is the z-average value of the radius of gyration of the molecule.
‡ $\langle S^2\rangle_w^{1/2}$ is the weight-average value of the radius of gyration of the molecule.

Molecular Dimensions of Linear Poly(ethylene) (Unperturbed)[a]

$\overline{M}_w$ ($\times 10^5$)	$(\langle r_0^2\rangle_w/\overline{M}_w)^{1/2}$ [nm/(g/mole)$^{1/2}$]	$\langle r_0^2\rangle_w/Dr_{max}$
1.25	0.192	7.80
2.69	0.215	9.86
4.65	0.190	7,73

[a] In tetralin at 105°C (378.2 K). $\langle r_0^2\rangle_w$ is the weight-average mean-square end-to-end distance in nm; $\overline{M}_w$ is the weight-average molecular weight; D is the diameter of a spherical segment of the lattice model chain; and r_{max} is the length of the fully extended chain (19); temperature dependence of $\langle r_0^2\rangle$ (in long chain paraffinic hydrocarbon solvents) is given by $-d\ln\langle r_0^2\rangle/dT = 1.2\times 10^{-3}$ (20).

Effect of Molecular Weight on Paraclustering[a]

Molecular weight of tagged molecules	$\frac{\sum_0}{\overline{M}_w} = \frac{\text{Molecular weight (neutrons)}}{\text{Molecular weight (g.p.c.)}}$	$\frac{\langle S^2\rangle_w^{1/2}}{\overline{M}_w^{1/2}}$†
3000	73 ± 7	0.41
12000	7 ± 1	0.18
60000	0.91 ± 0.1	0.049
140000	0.94 ± 0.1	0.042

[a] For deuterated poly(ethylene) in a protonated poly(ethylene) matrix with molecular weight ca. 100000 by neutron scattering measurements (21). All sample solution were blended in ortho-dichlorobenzene, quenched rapidly from the melt and measured at 25°C (298.2 K) (concentration of tagged molecules ≤ 5%).
† $\langle S^2\rangle_w^{1/2}$ the weight-average value of the radius of gyration of the molecule; values are in [nm/(g/mol)$^{1/2}$].

C. CRYSTALLINITY, CRYSTAL SIZE AND CRYSTALLIZATION KINETICS

Crystallinity[a,b]

	Average molecular weight	Density ρ (g/cm^3)	Melting point T (°C)	Degree of branching (CH_3/100C)	Crystallinity (α_ρ)	Crystal thickness l (nm)
Marlex 6015	15.0×10^4	0.980	131 (404.2)[c]	0.05	0.94	23.9
Hostalen GC	5.0	0.969	129 (402.2)	0.10	0.83	19.8
Hostalen GF	12.0	0.968	128 (401.2)	0.64	0.85	18.4
Hoechst PA-190	0.9	0.954	124 (397.2)	0.84	0.76	14.1
Alkathene HD	24.5	0.952	121 (394.2)	0.91	0.76	12.0
Epolene C-11	1.0	0.947	119 (392.2)	1.08	0.74	11.0
Lupolen KR 1051	5.1	0.943	120 (393.2)	1.30	0.70	11.4
BASF a Wachs	1.0	0.933	111 (384.2)	1.84	0.67	8.1
Lupolen KR 1032	5.3	0.931	115 (388.2)	2.50	0.60	9.2
Epolene C-13	1.0	0.919	104 (377.2)	2.80	0.54	6.5
Lupolene 1810 H	5.4	0.928	106 (379.2)	3.00	0.59	6.9
Hoechst PA-130	3.0×10^3	0.957	115 (388.2)	1.58	0.85	9.3
Epolene N-10	2.5	0.925	105 (378.2)	2.25	0.61	6.8
Epolene N-12	1.5	0.941	108 (381.2)	2.27	0.75	7.4
BASF a Wachs	5.6	0.936	106 (379.2)	2.32	0.68	6.9
Epolene N-11	1.5	0.934	104 (377.2)	2.48	0.68	6.6
Hoechst PA-560	6.0	0.914	101 (374.2)	4.10	0.51	6.1
Epolene C-10	7.0	0.919	99 (372.2)	4.19	0.60	5.8
Epolene C-101	3.2	0.936	104 (377.2)	4.42	0.70	6.6
Hoechst PA-520	2.0	0.917	102 (375.2)	4.90	0.54	6.2
Epolene C-12	3.7	0.906	83 (356.2)	6.94	0.50	5.1

[a] Depends upon chain branching; data given are representative values of typical commercial poly(ethylenes) (22).
[b] Crystallization from melt by rapid cooling at ambient temperature; crystallinity estimated from density.
[c] Values in parentheses indicate temperature in kelvin.

Single Crystal Lamella Thickness[a]

Solvent	Cryst. temp. (°C)	Conc. (%)	Long period (nm)	Refs.
HIGH DENSITY, POLY(ETHYLENE) (PHILLIPS MARLEX 50)				
Tetrachloroethylene	50 (323.2)[b]	0.31	11.2	24
	60 (333.2)	0.25	10.8	25
p-Xylene	72 (245.2)	0.46	11.0	26
	78 (351.2)	0.58	14.0	24
Xylene	50 (323.2)	–	9.25	23,26
	60 (333.2)	–	10.2	
	70 (343.2)	–	11.15	
	80 (353.2)		12.05	
	90 (363.2)		15.0	
	75 (348.2)	0.1	11.5	27
	80 (353.2)	0.1	12.5	
	85 (358.2)	0.1	13.3	
Melt	120 (393.2)	100	19.0	28
	125 (398.2)	100	22.3	
	130 (403.2)	100	35.5	
n-Butyl acetate	105 (378.2)	0.45	14.7	25
	110 (383.2)	0.57	16.2	24
Diphenyl ether	120 (393.2)	0.47	20.2	24
	125 (398.2)	0.37	17.3	25
LOW DENSITY POLY(ETHYLENE) (DUPONT ALATHON)				
Butyl stearate	111 (384.2)	0.25	12.6,15.5	23
	113.5 (386.7)	0.25	16.6	
Squalene	155.5 (428.7)	0.25	17.6	
Glycol dipalmitate	155.4 (428.6)	0.25	15.1	
	118 (391.2)	0.25	16.4	
	121 (394.2)	0.25	20.6	
Tripalmitin	121 (394.2)	0.25	18.8	

[a] Long periods from small angle X-ray scattering, effect of crystallization temperature and solvents (23).
[b] Values in parenthesis indicate temperature in kelvin.

Crystallization Kinetic Parameters See table "Rate of Crystallization of Polymer" in this Handbook, and Refs. 29–31.

D. EQUILIBRIUM THERMODYNAMIC PROPERTIES

Entropy of Fusion at Equilibrium Melting Temperature (J/mol/K)

	Value	Refs.
ΔS_u	9.81	32
	9.60	33
	9.91	34
At constant volume $(\Delta S_u)_v$	7.42	33
	7.72	35

Glass Transition Temperature[a,b] (°C)

Value	Refs.
-30 ± 15 (243.2 ± 15)[c]	37,38
-80 ± 10 (193.2 ± 10)	39
-128 ± 5 (145.2 ± 5)	40,41

[a] Ref. 36. See also Transition and Relaxation Temperatures in Section E.
[b] Considerable disagreement exists between different authors on the exact value of the transition which can be identified as the glass transition temperature. See Ref. 36 for a detailed discussion.
[c] Values in parentheses indicate temperature in kelvin.

Glass Transition Activation Energy 46–75 kJ/mol (42).

Heat Capacity, C_p (J/mol/K)[a]

Temperature (K)	Polymer	C_p	Refs.
298.15	Crystalline	21.70	
298.15	Amorphous	30.81	
300	Branched	32.55	43
		32.68	44
		32.86	45
300	Linear	23.93	46
		24.14	47
		24.24	46
400	Molten	34.48	48
		35.22	44,49
		35.36	50
		36.04	48

[a] Ref. 2. For linear, amorphous, crystalline and molten poly(ethylene), (0–600 K), see Table "Heat Capacity of High Polymers" in this Handbook, and also Refs. 2,34.

Heat Capacity in Liquid (2) For molten poly(ethylene) (390–600 K)
$C_p = 4.325 \times 10^{-2} T + 17.919$ [$\pm 1.2\%$ (RMS deviation)]

Heat Capacity in Amorphous Glass (2) The heat capacity of amorphous poly(ethylene) obtained from crystallinity extrapolations was given in J/mol/K.

From 0.5 to 20 K:

$$C_p = \exp[-0.135328(\ln T)^3 + 0.393949(\ln T)^2 + 2.85597(\ln T) - 7.84553]$$
$$[\pm 2.2\% \text{ (RMS deviation)}]$$

From 10 to 260 K:

$$C_p = \sum_{n=0}^{7} A_n T^n \quad [\pm 0.7\% \text{ (RMS deviation)}]$$

$A_0 = 1.0966333$ $A_1 = -0.11209575$
$A_2 = 9.3092851 \times 10^{-3}$ $A_3 = -1.7095906 \times 10^{-4}$
$A_4 = 1.5885817 \times 10^{-6}$ $A_5 = -7.931924 \times 10^{-9}$
$A_6 = 2.0248831 \times 10^{-11}$ $A_7 = -2.0616876 \times 10^{-14}$

Heat Capacity in Crystalline Solid (2) The heat capacity of crystalline poly(ethylene) obtained from extrapolated values was given in J/mol/K.

From 0.4 to 20 K:

$$C_p = \exp[-1.07155 \times 10^{-2}(\ln T)^3 + 4.62622 \times (\ln T)^2 + 2.89948(\ln T) - 9.12864]$$
$$[\pm 5.8\% \text{ (RMS deviation)}]$$

From 10 to 410 K:

$$C_p = \sum_{n=0}^{9} A_n T^n \quad [\pm 1.2\% \text{ (RMS deviation)}]$$

$A_0 = 1.1504009$ $A_1 = -0.19842302$
$A_2 = 1.2786634 \times 10^{-2}$ $A_3 = -2.4474207 \times 10^{-4}$
$A_4 = 2.593176 \times 10^{-6}$ $A_5 = 1.6647891 \times 10^{-8}$
$A_6 = 6.5926585 \times 10^{-11}$ $A_7 = -1.5679761 \times 10^{-13}$
$A_8 = 2.0474114 \times 10^{-16}$ $A_9 = -1.1252521 \times 10^{-19}$

Heat Capacity Change at Glass Transition Temperatures 10.5 J/mol/K at 237 K (2)

Heat of Fusion at Equilibrium Melting Temperature 4.1 ± 0.2 kJ/mol (2,51)

Residual Entropy of the Glassy State at 0 K $S_0 = 3.0$ J/mol/K (2).

E. OTHER GENERAL PHYSICAL PROPERTIES

Coefficient of Thermal Expansion[a]

Temp (°C)	Coefficient of expansion ($\times 10^5$) Linear	Cubical	Specific volume ratio (V_E/V_{25})[b]
−35 (238.2)[c]	10.0	30	0.969
−20 (253.2)	13.7	41	0.975
0 (273.2)	18.3	55	0.986
20 (293.2)	23.7	71	0.997
25 (298.2)	24.8	74	1.000
40 (313.2)	29.0	87	1.012
60 (333.2)	33.7	101	1.031
80 (353.2)	40.3	121	1.055
100 (373.2)	46.6	140	1.094
110 (383.2)	51.0	153	1.130
115 (388.2)	25.0	75	1.140
115–150 (388.2–423.2)	25.0	75	–
150 (423.2)	25.0	75	1.168

[a] Branched polyethylene (52,53); for data on amorphous linear poly(ethylene), see Ref. 40.
[b] V_E is relative excess volume, V_{25} is the volume at 25°C (273.2 K).
[c] Values in parentheses indicate temperature in kelvin.

Density[a] (Mg/m^3) ≡ (g/cm^3)

	Value	Refs.
Amorphous (from extrapolation of data above the melting point)	0.855	54
Commercial high-pressure poly(ethylene)	0.915–0.935	55
Experimental high-pressure poly(ethylene)	0.940–0.970	55
Ziegler process (Refs. 56,57) poly(ethylene)	0.940–0.965	55
Phillips process (Ref. 58) poly(ethylene)	0.960–0.970	55
Crystal density (theoretical)	See "Crystallographic Data and Crystallographic Modifications" in Section A	

[a] Unless otherwise stated, the values given are for 25°C (293.2 K); see also Sections G and H.

Dielectric Constant At 100 kHz and 23°C (296.2 K): 2.3 (59)

Effect of Density on Dielectric Constant[a]

Density (g/cm^3)	Dielectric constant (ASTM D 150)
0.920	2.28
0.925	2.29
0.930	2.30
0.935	2.31
0.940	2.32

[a] Ref. 60. The relationship shown in this table is for pure poly(ethylene). Therefore, considerable divergence from this relationship is caused by the presence of impurities as well as addition of additives such as carbon black or other fillers.

Dielectric Loss tan δ (1×10^{-4}–1×10^{-3}) (61,62). The values of tan δ depend on temperature and structure of poly(ethylene) (61).

Dielectric Strength[a]

Temperature (°C)	Value ($\times 10^6$) (V/cm)[b,c]
− 200 to 0 (73.2–273.2)[d]	7
50 (323.2)	5.3
100 (373.2)	1.8

[a] Ref. 63.
[b] Short-time test value (ASTM D149) is 16000–24000 V/cm, and depends upon sample configuration and impurities (64).
[c] Intrinsic dielectric strength of LDPE is of the order of 8.0×10^5 V/cm, if all chain end, surface and impurity effects are eliminated (64).
[d] Values in parentheses indicate temperature in kelvin.

Electrical Properties See also Section H (65).

Flash Ignition Temperature ASTM Method E136-58T: 340°C (613.2 K) (66).

Frictional Properties[a]

Coefficient of friction (μ)	Steel sliding on polymer		Polymer sliding on steel		Polymer sliding on polymer	
	Polished	Abraded	Polished	Abraded	Polished	Abraded
Static (M_S)	0.60	0.33	0.60	0.33	0.60	0.33
Kinetic (M_K)	0.60	0.33	0.60	0.33	0.60	0.33
	0.50	0.25				

[a] Ref. 67.

Heat of Combustion[a]

Density (Mg/m^3) ≡ (g/cm^3)	Methyl groups per 1000 C atoms	Heat of combustion ΔE (kJ/kg)
0.9391	8.3	− 46,412
0.9220	24.7	− 46,492
0.9053	46.2	− 46,542

[a] Ref. 68.

Heat of Fusion and Melting Temperature From Differential Thermal Analysis Data[a]

Poly(ethylene) type	Melting point (°C)	Heat of fusion (kJ/kg)	Refs.
Marlex 50 (Phillips, linear)	135 (408.2)[a]	245.3	69
Super-Dylan (Ziesler, linear)	130 (403.2)	218.6	69
DYNH			
(Union Carbide, branched)	112 (385.2)	140.6	69
Linear poly(ethylene)			
from dilatometric measurements		280.5	33
from calorimetric measurements		277.1	34,70

[a] Values in parentheses indicate temperature in kelvin.

Ignition Limiting Oxygen Indices (ILOI)[a]

650°C (923.2 K)	600°C (873.2 K)	550°C (823.2 K)
2.8 ± 0.1	3.5 ± 0.1	5.7 ± 0.1

[a] Ref. 71. The method used (ASTM D2863-70) is defined as the minimum volume fraction of oxygen required for ignition to occur.

Infrared Absorption Bands (72–79).
Far Infrared (80).

Intrinsic Viscosity See Section G.

Mechanical Properties See Section H.
Ultra-drawn polyethylene. See Refs. 81–90.

Elastic Compliance See Section G.

Elongation at Break (%) See Section H.

Hardness, Shore D See Section H.

Impact Strength, Izod See Section H.

Low Temperature Brittleness See Section H.

Tensile Modulus See Section H. Also see Ref. 91 for Young's, shear and bulk moduli for more than 1,100 poly(ethylene) samples reported (within density range from 0.90 to 0.98 g/cm^3).

Tensile Strength See Section H.

Melt Index See Section G.

Melt Viscosity See Section G.

Melting Temperature[a,b] (°C)

	Value	Refs.
Poly(methylene)	136.5 ± 0.5 (409.7 ± 0.5)[c]	92
Linear poly(ethylene)	137.5 (410.7)	33
Linear poly(ethylene), high molecular weight fraction	138.5 (411.7)	93
From extrapolation of MP of *n*-Paraffins	141 ± 2.4 (414.2 ± 2.4)	94
T_m^0 (∞ MW)[b]	141.4–145.5 ± 1 (414.6–418.7 ± 1)	30

[a] See also Section G and under Section F (Effect of chain branching on melting temperature).
[b] The estimated melting point of the infinite poly(ethylene) crystal is in dispute (see Refs. 30,95).
[c] Values in parentheses indicate temperature in kelvin.

Molecular Properties of Typical Poly(ethylenes)[a]

Polymer	$\overline{M}_w$ ($\times 10^{-3}$)	Density (g/cm^3)	Groups per 100 carbon atoms				
			CH_3–	–CH_2CH_3	–CH=CH_2	–CH=CH–	=C=CH_2
Ziegler	50–60	0.960	3.6	0.5	0.09	<0.02	0.06
Phillips	50–60	0.965	3.1	0.8	1.58	<0.02	0.08
Solution polymerization	50–60	0.964	3.2	0.5	0.42	<0.02	0.03
Phillips catalyst gas phase	350	0.954	2.8	<0.2	0.65	<0.02	0.04
Low-density PE		0.918–0.928	20–33	6–9	0.08–0.25	<0.02–0.06	0.17–0.33

Permeability and Diffusion Constants See corresponding table in this Handbook, and also Refs. 112,113.

Permeabilities at 30°C (293.2 K) of Poly(ethylene)[a]

Crystallinity (%)	Permeability $\left[\frac{(cm^3\ STP)\ mm \times 10^{10}}{cm^2\ s\ (cm\ Hg)}\right]$			
	N_2	O_2	CO_2	H_2O[b]
60	1.90×10^{-9}	5.5×10^{-9}	35.2×10^{-9}	80×10^{-9}
90	0.66	2.1	7.4	–
78	0.33	1.1	4.3	–
81	0.27	1.06	3.5	13

[a] Ref. 114.
[b] 90% e.h. at 25°C.

Raman Spectra See Refs. 115–123.

Refractive Index n_D^{25}

	Value	Refs.
LDPE	1.51	124
MDPE	1.52	124
HDPE (melt index above 0.1)	1.54	124
Amorphous, n_{5461}^{25}	1.49	125
Crystal, $\alpha \approx \beta$[a]	1.520	125
γ[a]	1.582	122

[a] α, β and γ are refractive indices along the *a*, *b* and *c* crystallographic directions of the crystal, respectively.

Dependence of Refractive Index on Chain Branching, Crystallinity and Density See Section F (Effect of Chain Branching on Physical Properties).

Specific Refractivity[a]

Temp. (°C)	v (cm^3/g)	n	r
LOW DENSITY POLY(ETHYLENE) (ALATHON-10)			
90 (363.2)[b]	1.159	1.4801	0.3293
100 (373.2)	1.178	1.4693	0.3283
108 (381.2)	1.209	1.4575	0.3297
113 (386.2)	1.239	1.4432	0.3286
118 (391.2)	1.250	1.4392	0.3289
124.4 (397.6)	1.256	1.4368	0.3288
			Av. 0.3290
HIGH DENSITY POLY(ETHYLENE) (MARLEX 50)			
130 (403.2)	1.261	1.4327	0.3273
139.9 (413.1)	1.270	1.4297	0.3297
150.6 (423.8)	1.281	1.4261	0.3283

[a] $r = \nu(n^2 - 1)/(n^2 + 1)$, where ν and n are specific volume and refractive index respectively. Ref. 52.
[b] Values in parentheses indicate temperature in kelvin.

Refractive Index Increment (dn/dc) See corresponding table in this Handbook, and also Refs. 126–133.

Softening Temperature, Vicat See Section H.

Solvent–Nonsolvent Systems for Fractionation

Solvent	Nonsolvent	Refs.
Xylene	Triethylene glycol	134,135
p-Xylene	Ethylene glycol monoethylene ether	136
Tetralin	2-Butoxyethanol	137
	Poly(ethylene oxide) [mol. wt. 200]	138,139

Transition and Relaxation Temperatures[a]

Designation	Temperature range (°C)	Approximate activation energy (kJ/mol)	Refs.
α	60–80 (333.2–353.2)[b]	>420	
β	– 20 to – 30 (253.2–243.2)	160–200	141
γ	– 80 to – 90 (193.2–183.2)[c]	46–75	
	– 120 to – 130 (153.2 –143.2)	32	

[a] There is considerable disagreement in the literature on the phenomena associated with the various transition and relaxation temperatures observed. Transition temperatures and temperatures associated with peaks in dynamic loss are collected together under the above combined heading. The transition and relaxation temperatures associated with amorphous regions of branched and linear poly(ethylenes) are designated as α, β, γ, etc. in the descending temperature order (140).
[b] Values in parentheses indicate temperature in kelvin.
[c] These frequently merge depending upon the crystallinity and frequency of the test method.

Frequency Dependence of Relaxation Temperatures in Dynamic Mechanical Loss Measurements[a]

α		β		γ	
Hz	T (K)	Hz	T (K)	Hz	T (K)
HIGH PRESSURE, BRANCHED POLY(ETHYLENES)

Viscosity–Molecular Weight Relationship See corresponding table in this Handbook, and Ref. 52.

F. EFFECT OF CHAIN BRANCHING (SHORT) ON PHYSICAL PROPERTIES

Effect on Density and Refractive Index[a]

Methyl groups per 1000 C atoms	Density (Mg/m^3) ≡ (g/cm^3)	Refractive index n_D^{25}
83	0.91	1.5060
48	0.917	1.5168
46	0.925	1.5152
26	0.929	1.5227
16	0.926	1.5260

[a] Refs. 143, 52.

Effect on Expansion Coefficient (Mean) and Specific Volume of Crystalline Phase[a]

Methyl groups per 1000 C atoms	$1/V_{20}$ (– 150 to 100°C)	$(\Delta V/\Delta T)(\times 10^{-4})$ (0–100°C)	V_{20}
0.3	2.47	3.13	1.001
2	2.59	2.95	0.998
17.5	2.61	2.98	1.010
23	2.84	3.42	1.009
37	2.96	3.70	1.017

[a] Ref. 52,144.

Effect on Long Period Spacings and Crystallinity of Completely Annealed Samples[a]

Poly(ethylene)	Methyl groups per 1000 C atoms	Long period spacing (nm)	% crystallinity	Refs.
Branched (high pressure)	60	22.0	21	146
	45	20.0	48	
	35	21.0	50	
	28	22.0	53	
	20	23.0	56	
	15	25.0	59	
	10	26.0	62	
Linear	7	32.0	77	143,144
(Ziegler type catalysts)	5	36.0	79	
Linear	2	42.0	88	58
(Phillips petroleum process)				

[a] Ref. 52,145.

Effect on Melting Point Observed[a]

Methyl groups per 1000 C atoms	Melting point (°C)
87	105 (378.2)[b]
28	113 (386.2)
28	108 (381.2)
8	123 (396.2)
0	132 (405.2)

[a] Both the amount and randomness of branching affect the melting point. Experimental conditions used for the following data were not adequate for equilibrium crystallinity and accuracy of melting points (52).
[b] Values in parentheses indicate temperature in kelvin.

G. PROPERTIES OF A SERIES OF SELECTED POLY(ETHYLENE) SAMPLES

			Infrared functional groups

A. CRYSTALLOGRAPHIC DATA AND MODIFICATIONS OF ISOTACTIC POLYPROPYLENES

Stereoisomeric form	Crystal system	Space group	Lattice dimensions (nm) a	b	c	α, β, or γ	Number of chains per unit cell	Molecular conformation	Crystal density (g/cm³)	Refs.
Isotactic	Monoclinic α	C2/C	0.665	2.096	0.650	$\beta = 99.33°$	4	Helix(3/1)	0.936	1
	Monoclinic α_1	C2/C	0.666	2.078	0.6495	$\beta = 99.62°$	4		0.946	2–4
	Monoclinic α_2	$P2_1/C$	0.666	2.078	0.6495	$\beta = 99.62°$	4	$(TG)_3$	0.946	2–4
	Hexagonal β		1.274		0.635	$\gamma = 120°$	9	Helix(3/1)	0.921	5,6
	Hexagonal β_1		0.636		0.635	$\gamma = 120°$	9	$(TG)_3$	0.921	7
	Hexagonal β_2		1.908		0.649	$\gamma = 120°$	9		0.922	2,8
	Triclinc γ		0.654	2.14	0.650	$\alpha = 89°$, $\beta = 99.6°$, $\gamma = 99°$	2	Helix(3/1) $(TG)_3$	0.954	9
	Quenched "smectic"							Helix(3/1) $(TG)_3$		1,10–13

B. CRYSTALLOGRAPHIC DATA AND MODIFICATIONS OF SYNDIOTACTIC POLYPROPYLENES

Stereoisomeric form	Crystal system	Space group	Lattice dimensions (nm) a	b	c	α, β, or γ	Number of chains per unit cell	Molecular conformation	Crystal density (g/cm³)	Refs.
Syndiotactic	Orthorhombic observed in fibers	$C222_1$	1.450	0.580 or 0.560	0.740		2	Helix(4/1) $(T_2G_2)_2$	0.90	14–16
	Orthorhombic high temp. form	Ibca	1.450	1.120	0.740		2	Helix(4/1) $(T_2G_2)_2$	0.90	17–19
	Orthorhombic low temp. form		0.522	1.117	0.506		2	Planar Zigzag	0.945	20–22
	Triclinic	P1	0.572	0.764	1.16	$\alpha = 73.1°$, $\beta = 88.8°$, $\gamma = 112.0°$	1	$T_6G_2T_2G_2$	0.939	23

*Based on a table in the third edition, by R. P. Quirk and M. A. A. Alsamarraie, The Maurice Morton Institute of Polymer Science, University of Akron, Akron, Ohio.

C. DIMENSIONS OF POLY(PROPYLENE) MOLECULES*

Effect of Molecular Weight on Radius of Gyration[a]

Method of Crystallization	PPH matrix $\bar{M}_w$ ($\times 10^3$)	PPD matrix[b]				
		$\bar{M}_w$ ($\times 10^3$)	$\bar{M}_w/\bar{M}_n$	$\langle S^2\rangle_z^{1/2}$† (nm)	$\langle S^2\rangle_w^{1/2}$† (nm)	$\langle S^2\rangle_w^{1/2}/\bar{M}_w^{1/2}$‡

[a] Measured by neutron scattering. Polymer >97% isotactic; Ref. 26.
[b] Deutrated poly(propylene).
† $\langle S^2\rangle_z^{1/2}$ and $\langle S^2\rangle_w^{1/2}$ are the z-average and weight-average values, respectively, of the radius of gyration of the molecule.
‡ In nm/(g/mol)$^{1/2}$.

Neutron Scattering Measurements

Method of crystallization	$\langle S^2\rangle_w^{1/2}/\bar{M}_w^{1/2}$†	
	Melt	Crystalline
Rapidly quenched	0.035	0.034
Isothermally crystallized at 139°C (412.2 K)	0.035	0.038
Rapidly quenched from melt and subsequently annealed at 137°C (410.2 K)	0.035	0.036

†$\langle S^2\rangle_w^{1/2}$ is the weight-average value of the radius of gyration of the molecule; values are in nm/(g/mol)$^{1/2}$. For further details and analysis, see Refs. 27–30.

Neutron Scattering See Refs. 24–30.

D. CRYSTALLINITY AND CRYSTALLIZATION KINETICS

Crystallinity and Melting Point of Samples from Multiple Solvent Fractionation[a]

Solubility of fractions in boiling solvents			
Soluble in	Insoluble in	T_m (°C)	Wide angle X-ray crystallinity (%)
–	Trichloroethylene	176 (449.2)[b]	75–85
–	n-Octane	174–175 (447.2–448.2)	65–85
n-Octane	2-Ethylhexane	174–175 (447.2–448.2)	60–66
2-Ethylhexane	n-Heptane	168–170 (441.2–443.2)	52–64
n-Heptane	n-Hexane	147–159 (420.2–432.2)	41–54
n-Hexane	n-Pentane	110–135 (383.2–408.2)	25–37
n-Pentane	Diethyl ether	106–114 (379.2–387.2)	15–27

[a] Refs. 31,32.
[b] Values in parenthesis indicate temperature in kelvin.

* See also corresponding table in this Handbook, and Refs. 24,25.

Crystallinities and Melting Temperatures of Mixtures of Amorphous[a] and Isotactic Poly(propylene)[b,c]

Isotactic fraction (%)	Crystallinity Calculated	Measured	Melting temperature (°C)
100	67.2	67.7	174 (447.2)[d]
87.5	59.3	60.3	173 (446.2)
75.8	51.4	49.8	172–173 (445.3–446.2)
60	40.6	40.2	171–172 (444.2–445.2)

[a] Ether extract.
[b] 2-Ethylhexane extraction residues.
[c] Refs. 33,34.
[d] Values in parenthesis indicate temperature in kelvin.

Crystallinity in Isotactic Poly(propylenes)[a]

Sample	Description and condition	Crystalline weight fraction
1.	Heptane extract of crude polypropylene, "amorphous", highly atactic	0.14
2.	Isotactic, water quenched	0.31
3.	Same as 2, followed by annealing at 105°C for 1 hr	0.43
4.	Same as 2, followed by annealing at 160°C for 1/2 hr	0.65

[a] Ref. 35,36.

Effect of Isotacticity on Crystallinity[a]

Sample	Description and condition	Crystalline weight fraction
1.	$\bar{M}_w = 202000$, $\bar{M}_w/\bar{M}_n = 2.6$, Isotacticity = 0.988	0.42–0.75
2.	$\bar{M}_w = 159000$, $\bar{M}_w/\bar{M}_n = 2.3$, Isotacticity = 0.978	0.40–0.75
3.	$\bar{M}_w = 189000$, $\bar{M}_w/\bar{M}_n = 3.0$, Isotacticity = 0.953	0.38–0.60
4.	$\bar{M}_w = 209000$, $\bar{M}_w/\bar{M}_n = 1.8$, Isotacticity = 0.882	0.30–0.45
5.	$\bar{M}_w = 190000$, $\bar{M}_w/\bar{M}_n = 1.6$, Isotacticity = 0.787	0.20–0.25

[a] Ref. 37.

Crystallization Kinetics See Table "Rate of Crystallization of Polymers" and Refs. 38–49 for isotactic poly(propylene), and Refs. 50–52 for syndiotactic poly(propylene).

E. EQUILIBRIUM THERMODYNAMIC PROPERTIES

Equilibrium Melting Temperature, T_m

Isotactic poly(propylene) 187.5°C (460.7 K) for the crystal with an infinite size [reported data ranging from 183°C–220°C (456–493 K); for a detailed discussion, see Ref. 34]. It is also critically dependent upon the isotacticity in crystalline samples.

Effect of Isotacticity on Equilibrium Melting Temperature[a]

Sample	Description and condition	Equilibrium melting temperature (°C)
1.	$\bar{M}_w = 202000$, $\bar{M}_w/\bar{M}_n = 2.6$, Isotacticity = 0.988	183.8 (457.0)[b]
2.	$\bar{M}_w = 159000$, $\bar{M}_w/\bar{M}_n = 2.3$, Isotacticity = 0.978	182.8 (456.0)
3.	$\bar{M}_w = 189000$, $\bar{M}_w/\bar{M}_n = 3.0$, Isotacticity = 0.953	180.2 (453.4)
4.	$\bar{M}_w = 209000$, $\bar{M}_w/\bar{M}_n = 1.8$, Isotacticity = 0.882	173.0 (446.2)
5.	$\bar{M}_w = 190000$, $\bar{M}_w/\bar{M}_n = 1.6$, Isotacticity = 0.787	163.0 (436.2)

[a] Ref. 37.
[b] Values in parenthesis indicate temperature in kelvin.

Syndiotactic poly(propylene) Equilibrium melting temperature is critically dependent upon the tacticity of the samples. For a sample with 95% of [r], 92% of [rr], and 86% of [rrr], and molecular weight higher than 40000, for example, the equilibrium melting temperature is 160°C (433.2 K) (53,54). For a 99% dyad sample, an actual melting temperature of 163°C (436.2 K) can be observed (55).

Equilibrium Enthalpy of Fusion, ΔH_f

Isotactic poly(propylene) 8.7 ± 1.6 kJ/mol (56) [reported data ranging from 2.65 kJ/mol to 10.94 kJ/mol; for a detailed discussion see Ref. 56].

Syndiotactic poly(propylene) Equilibrium enthalpy of fusion is determined for samples with 95% of [r], 92% of [rr], and 86% of [rrr], and molecular weight higher than 40000, and is 8.0 kJ/mol (53).

Equilibrium Entropy of Fusion, ΔS_f

Isotactic poly(propylene) 18.9 ± 3.5 J/K/mol (56).

Syndiotactic poly(propylene) No data is available.

Glass Transition Temperature, T_g

Isotactic poly(propylene) − 3.2°C (270 K) (56). The agreement of T_g values from various experimental methods [*e.g.*, dilatometry, dynamic mechanical measurements (at low frequency), heat capacity and NMR (narrowing of line width)] is not very good, but ranges from about − 30 to + 20°C. The glass transition temperature depends on thermal history (may also be tacticity) of the sample (57–61). Activation energy, 117–152 kJ/mol (57).

Syndiotactic poly(propylene) May be close to the glass transition temperature of isotactic poly(propylene).

Heat Capacity, C_p (J/K/mol) See "Thermodynamic Properties" in this Handbook, and Ref. 62.

References page V-28

Isotactic poly(propylene) in the liquid The amorphous liquid heat capacities above T_g are given in J/K/mol [±2.5% (RMS)] $C_p = 0.151291\,T + 42.956$

Isotactic poly(propylene) in the solid The heat capacities in the solid state are separately fitted to 100% crystalline in various temperature ranges, all in J/K/mol:

10–100 K [±0.4% (RMS)]:
$C_p = \exp[0.241028(\ln T)^3 - 3.01364(\ln T)^2 + 13.5529(\ln T) - 18.7621]$
80–250 K [±0.8% (RMS)]:
$C_p = \exp[0.121683(\ln T)^3 - 1.90162(\ln T)^2 + 10.727(\ln T) - 17.6875]$
230–350 K [±1.7% (RMS)]:
$C_p = 1.5912 \times 10^6\,T^2 + 0.3837\,T - 64.551$

The 0% crystalline amorphous state heat capacities in various temperature ranges, all in J/K/mol.

10–60 K [±1.0% (RMS)]:
$C_p = \exp[0.327068(\ln T)^3 - 3.688(\ln T)^2 + 14.7469(\ln T) - 18.4281]$
50–180 K [±0.7% (RMS)]:
$C_p = \exp[0.00742669(\ln T)^3 - 0.189318(\ln T)^2 + 2.10843(\ln T) - 3.0699]$
160–260 K [±1.1% (RMS)]:
$C_p = \exp[0.0727139(\ln T)^3 - 0.711627(\ln T)^2 + 2.31907(\ln T) + 0.77926]$

Syndiotactic poly(propylene) No data is available.

Heat Capacity Data in the Crystalline and Amorphous Isotactic Poly(propylene)

	C_p (J/K/mol)		
Temperature (K)	Crystalline	Amorphous	Refs.
50	13.00	15.22	53
100	26.51	28.21	53
150	37.68	39.53	53
200	47.47	50.53	53
250	56.53	61.95	53
300	70.39	84.11	53
350	82.12	109.2	53

Heat Capacity Changes at Glass Transition Temperatures (J/K/mol)

Isotactic poly(propylene) 19.2 J/K/mol at −3.2°C (270 K) (63).

Syndiotactic poly(propylene) May be close to that of isotactic poly(propylene).

Residual Entropy of the Glassy State at 0 K S_0 (J/K/mol)

Isotactic poly(propylene) 5.2 J/K/mol (58).

Syndiotactic poly(propylene) No data is available.

F. OTHER GENERAL PROPERTIES

Coefficients of Thermal Expansion (ASTM D 696) (K^{-1}) (Refs. 64–66)

From −30°C (243.2 K) to 0°C (273.2 K)	6.5×10^{-5}
From 0°C (273.2 K) to 30°C (303.2 K)	10.5×10^{-5}
From 30°C (303.2 K) to 60°C (333.2 K)	14.5×10^{-3}

Density at 25°C (298.2 K) (Mg/m^3) = (g/cm^3). See also Section G.

Isotactic	Crystalline	0.932–0.943
	Amorphous (from extrapolation of data above melting point)	0.850–0.854
	"Smectic" form	0.916
Syndiotactic	Crystalline	0.989–0.91
	Amorphous (from extrapolation of data above melting point)	0.856

Dielectric Constant See Section G.

Electrical Properties: Conductivity[a]

Electric field (kV/cm)	Crystallinity (%)	Conductivity at 72°C (mhos/cm)	Refs.
8.5	–	1×10^{-18}	67
10.5	75	3.2×10^{-16}	68
	45	7.4×10^{-17}	68
	78	2.3×10^{-18}	69
	50.5	1×10^{-18}	69
24	81.2	2×10^{-16}	70
	39.7	1×10^{-16}	70
	78	2.2×10^{-18}	69
	50.5	1×10^{-18}	69
48	–	3.2×10^{-18}	71
	78	2.3×10^{-18}	69
144	81.2	1×10^{-14}	70
	39.7	1×10^{-14}	70
	78	2.8×10^{-18}	69
	50.5	2×10^{-18}	69

G Values for Radiation Crosslinking G(c.l.) and Chain Scission G(Breaks)
Maximum and Minimum Values[a]

	G(breaks)		G(c.l.)	
	Maximum	Minimum	Maximum	Minimum
Atactic	0.24	0.10	0.27	0.115
Isotactic film	0.21	0.10	0.14	0.069
Isotactic flake	0.27	0.10	0.18	0.068

[a] Ref. 72.

At Room Temperature and in Vacuum[a]

	G(c.l.)		G(breaks)
Measured by	Solubility	Elasticity	Solubility or viscosity
Atactic	0.12–0.27	0.6–1.3	0.10–0.24
Isotactic	0.07–0.25		0.10–0.24
	0.6		0.9
			5.0

[a] Ref. 72.

G-Values in Terms of Radiolytic Gas Yields[a]

	Gas	Irradiation T (°C)	G (gas)
Atactic	H_2	25	2.34
	CH_4	25	0.095
Isotactic	H_2	− 196	2.55
	CH_4	− 196	0.058
	H_2	25	2.78
	CH_4	25	0.072

[a] Ref. 72.

Ignition Limiting Indices[a]

650°C (923.2 K)	600°C (873.2 K)	550°C (823.3 K)
2.8 ± 0.1	3.5 ± 0.1	5.7 ± 0.1

[a] This method (ASTM D2803-70) is defined as the minimum volume of oxygen required for ignition to occur; Ref. 73.

Infrared Absorption Bands (36,74–85)

Assignment in Infrared Spectrum Used for Crystallinity Measurements[a,b]

Form	Crystalline phase wave numbers (cm^{-1})	Amorphous phase wave numbers (cm^{-1})
Isotactic	809	790
	842	1158
	894	
	997	
Syndiotactic	866	1131
	977	1199
		1230

[a] Used for tacticity measurements: ratio of absorption at 997 cm^{-1} to that at 975 cm^{-1} (80,84,86).
[b] Ref. 36.

Sequence-Sensitive Vibration Band of Propylene Units[a]

Position of band (cm^{-1})	Type of regularity	Classification	n^b
998	Isotactic	Helix band	10–12
973	Isotactic	Regularity band	3–4
841	Isotactic	Helix band	12
977	Syndiotactic	Helix band	
962	Syndiotactic	Regularity band	
867	Syndiotactic	Helix band	
936	–	Band of isolated propylene unit	

[a] Refs. 74,87.
[b] Number of the units in sequence for the bands to appear.

Far Infrared. See Ref. 88.

Mechanical Properties: Elongation at Break See Sections G and H

Hardness, Shore D See Sections G and H.

Impact Strength, Izod See Sections G and H.

Low Temperature Brittleness See Sections G and H.

Melt Index (ASTM Method D 1238-57T)

Molecular weight ($\times 10^3$)	Melt index (230°C, 2.16 kg)
142	22.8
180	7.3
220	3.5
292	1.2
358	0.39

Molecular Parameters of Typical Poly(propylenes) (64)

Number of double bonds per 1000 C atoms	<1
Type of unsaturation	Vinylidene
$\bar{M}_w$	220000–700000
$\bar{M}_n$	38000–60000
$\bar{M}_w/\bar{M}_n$	5–12

Nuclear Magnetic Resonance See Refs. 80,89–94.

Permeability and Diffusion Coefficients See corresponding table in this Handbook and Refs. 95–97.

Permeability of Polypropylene Films to Various Gases[a]

	Permeability[b] (cm^3/24 hr/100 in.^{2}/mil/atm)		
Film	O_2	CO_2	N_2
Unoriented	250	800	40
Oriented	105–150	300–500	10–25

[a] Ref. 98.
[b] At 25°C (298.2 K) adn 50% rh (ASTM D 1434–63).

Properties of Typical Poly(propylenes) See Sections G and H.

Refractive Index $n_D^{25} = 1.49$ (66,99).

Refractive Index Increment (dn/dc) See corresponding table in this Handbook, and Refs. 30,100.

Softening Temperature, Vicat See Sections G and H.

Sound Velocity (m/s) (101–103).

Unoriented:	at 25°C (298.2 K)	2.5×10^3
	at 125°C (398.2 K)	125×10^3

Specific Heat See Heat Capacity.

Specific Volume (cm^3/g)[a]

Form	v_a (Amorphous)	v_b (Crystalline)
Isotactic	1.176–1.172	10.73–1.060
Smectic		1.092
Syndiotactic	1.165	1.114–1.10

[a] Ref. 64.

Tensile Modulus See Sections G and H.

Tensile Strength See Sections G and H.

Transition and Relaxation Temperatures Associated with Peaks in Dynamic Loss[a]

Transition	T (°C)	Assignment and remarks
α	30–80	Difficult to resolve
β (at 0.2 Hz)	0 (273.2)[b]	Insensitive to changes in crystallinity; long chain motion in amorphous portion
γ	− 80 (193.2)	In atactic poly(propylene); hindered movement of C–CH_3 units
δ	< − 200 (< 73.2)	Hindered rotation of CH_3 groups

[a] Designated as α, β, γ, etc. in order of descending temperatures; Ref. 104.
[b] Values in parentheses indicate temperatures in kelvin.

Ultra-Drawn Polypropylene See Refs. 105–108.

Viscosity–Molecular Weight Relationship See corresponding table in this Handbook.

G. PROPERTIES OF TYPICAL MAINLY ISOTACTIC POLY(PROPYLENES)[a,b]

Property	Value
Brittleness [D 746] (°C (K))	25 (298.2)
Deflection temperatures [D 648] (°C (K))	
at 66 lb/in^2 (4.64 kg/cm^2)	96–110 (369.2–383.2)
at 264 lb/in^2 (18.6 kg/cm^2)	57–63 (330.2–336.2)
Density [D 792] (Mg/m^3) = (g/cm^3)	0.90–0.91
Dielectric constant at 1 kHz [D 150]	2.2–2.3
Dielectric strength [D 149] (V/mil)	610 [430 at 120°C (393.2 K)]
(V/cm) × 10^{-3}	240 [170 at 120°C (393.2 K)]
Dissipation factor (60 Hz–100 MHz) [D 510]	3×10^{-4} – 1×10^{-3}
Elongation at break [D 638] (%)	500–900 [30 at − 40°C (233.2 K)]
Environment stress cracking or F_{50} time [D 1693]	Does not stress crack
Flexural modulus [D 790] (MPa) = (N/mm^2)	1172
Hardness, shore D [D 1706]	70–80
Heat capacity (kJ/kg/K)	1.926 (see also Table I)
Izod impact strength [D 256] (ft lb/in of notch)	0.4–6.0 [0.1–0.7 at − 20°C (253.2 K)]
(cm kg/cm notch)	2.2–12 [0.55–3.9 at − 20°C (253.2 K)]
Power factor at 1 kHz	< 0.002–0.001
Solvent resistance to hydrocarbons and chlorinated hydrocarbons	Resistant below about 80°C (353.2 K)
Stiffness in flexure [D 747] (MPa) = (N/mm^2)	1172
Tensile modulus [D 638] (MPa) = (N/mm^2)	1032–1720
Tensile strength [D 638] (MPa) = (N/mm^2)	29.3–38.6
Tensile yield elongation [D 638] (%)	11–15 [11% at − 40°C (233.2 K)]
Thermal conductivity [C 177] (W/m/K)	11.7
Vicat softening temperature [D 1525] (°C (K))	138–155 (411.2–428.2)
Volume resistivity [D 257] (Ω cm)	10^{16}–10^{17}

[a] Properties at ambient room temperature, unless denoted otherwise. The numbers in square brackets in the first column refer to the ASTM (American Society for Testing Materials) Standards.
[b] Refs. 64,66,99.

H. PROPERTIES OF SOME COMMERCIAL POLY(PROPYLENE) GRADES[a]

		Grade			
Property[b]	Method[c]	Pipes and sheets	Films	Injection molding	Cast and tubular film

A. INTRODUCTION

Fluoropolymers are divided into two sub-classes: (a) Fluorocarbon polymers, i.e., those that are made from perfluoromonomers, and (b) All the others that are made from monomers or comonomer systems that contain hydrogen, chlorine, or both, along with enough fluorine so that it contributes significantly to the properties and performance of the polymer. At times, the term fluorocarbon or fluorocarbon polymers, are used improperly to include all of the fluorine-containing polymers.

The commercially important fluorocarbon polymers are poly(tetrafluoroethylene) (PTFE), poly(tetrafluoroethylene-*co*-hexafluoropropylene) (FEP), poly[tetrafluoroethylene-*co*-(perfluoroalkylvinyl ether)] (PFA), and amorphous fluoropolymer (AF), typically copolymers of tetrafluoroethylene and fluorinated dioxole. The second group of fluoropolymers includes modified poly(tetrafluoroethylene-*co*-ethylene) (ETFE), poly(vinylidene fluoride) (PVDF) (sometimes referred to as PVF2), and copolymers of vinylidene fluoride, poly(chlorotrifluoroethylene) (PCTFE), poly(chlorotrifluorethylene-*co*-ethylene) (E/CTFE) and poly(vinyl fluoride) PVF.

The wide range of fluorine content in the various fluoropolymers (from 76 down to 39 weight percent fluorine), details of crystallinity, conformation, molecular weight, and other aspects of structure result in ranges of properties so wide that a single table listing all the materials and their properties is very cumbersome to use. Tables on the various materials are separated, therefore, with a short general comment on each material or class, at the beginning of each table. Each table has its own notes and list of references.

B. PHYSICAL CONSTANTS OF POLY(TETRAFLUOROETHYLENE) $-(CF_2CF_2)-$

Polytetrafluoroethylene (PTFE) was the first fluorocarbon polymer to be made and still retains the major part of the total business. The extremely high melt viscosity of PTFE having a molecular weight high enough for most applications precludes use of conventional methods of processing that require molten polymer. As a result, innovative procedures, quite different but not difficult, were devised to prepare useful objects. Some properties of PTFE reflect the unusual methods of processing.

NOTES

1. Many of the properties of PTFE are not constant but change systematically with crytalline content, molecular weight, void content, temperature, pressure, or some other independent variable. Where available, these inter-relationships are shown even though they are usually empirical rather than fundamental. Throughout the table, %C indicates percent crystallinity by weight.
2. American Society for Testing and Materials (ASTM) standards on the fluoropolymers provide a convenient source for information on details of the nature of a particular fluoropolymer, typical properties, methods of testing, and the like. For this reason, pertinent Standard numbers are included in the tables for each polymer. The fluoropolymer standards are the responsibility of the Fluoropolymers Section of the Materials Subcommittee of the Technical Committee on Plastics. The numerical designation is D-20.15.12. More recently, the International Organization for Standardization (ISO) has issued materials standards which incorporate various aspects of the ASTM standards.
3. The exact value depends on the particular type or grade of polymer that is being used.
4. Equations based on time–temperature superposition are given in Ref. 42 for PTFE with a crystalline content of approximately 58%. These relationships permit calculation of tensile creep modulus at any stress, time, or temperature in the temperature range of 35–100°C and stress levels below the elastic limit. Ref. 41 provides similar data over a wider range of conditions.

References page V-39

5. Reference 83 gives a value of 2.060 for the amorphous density of PTFE. Internal inconsistencies in this paper, however, need clarification before this writer can accept the value given.
6. Precise measurements of dielectric loss (Ref. 71) show peaks that correspond to the gamma transition. The measured values of tan delta, however, were all less than 300×10^{-6} with some as low as 20×10^{-6}.
7. No carbon track is formed.
8. Infrared methods show presence of carboxylic acid monomer and dimer, perfluorovinyl, and acid fluoride end groups in low molecular weight products (Ref. 9). The methods currently available are not sufficiently sensitive for quantitative work in polymers of commercially useful molecular weights, but the acid monomer and dimer ends have been found in commercial materials using FTIR procedures (Ref. 93).
9. This numerical rating for flame spread is not intended to reflect hazards presented by this or any other material under actual fire conditions.
10. The values given are selected from extensive tables and plots of data in Ref. 44.
11. The mechanical loss factor is related to the transition behavior. The value depends on temperature and frequency of the dynamic mechanical stress, values of the logarithmic decrement up to 0.55 have been observed (see Ref. 53).
12. This relationship is applicable only to PTFE, with molecular weights well below that required for the applications of plastics (see Ref. 78).
13. The temperature observed for the first (irreversible) melting point decreases with rate of heating. It also differs with the type of polymer. Evidence in Refs. 39 and 72 suggests that details of DSC scan for a first melting reflect aspects of molecular weight and molecular weight distribution.
14. Inconsistencies in the results from various laboratories for the heat of fusion of PTFE and FEP have not been resolved. Some aspects are discussed in Refs. 86, 89, and 90.
15. Standard Specific Gravity (SSG), described in ASTM D4894, D4895 and ISO 12086-1 (see Ref. 18 and 77), is a useful inverse measure of relative molecular weight for homopolymers of TFE. Many commercial polymers today, however, contain very small amounts of modifiers that affect the rate and extent of crystallization. With these materials, therefore, SSG is meaningful as a measure of relative molecular weight only within a given family of PTFE resins. Estimating actual values of the molecular weight of the highest molecular weight commercial polymers has, to date, involved assumptions and extrapolation. These relationships, therefore, are, at best, a first approximation. In addition, some references, such as Refs. 11 and 40, give relationships for molecular weight as a function of SSG with little or no documented basis for the equation.
16. The recommended maximum service temperature is 260°C (Ref. 21). There are, however, examples of satisfactory use at higher temperatures. Gaskets in totally enclosed systems, for instance, are used repeatedly at 500°C and 15 000 psi (103 MPa) (see Ref. 19). PTFE also performs well at low temperatures. In compressive strength tests at 4 K, for example, the polymer has been shown to have ductile rather than brittle failure (Ref. 95).
17. Weight gain is noted with some chlorinated and fluorinated liquids that contain no hydrogen (Ref. 82). The weight increase decreases with increasing crystallinity (Ref. 78).
18. PTFE is inert to essentially all common chemicals (see Refs. 64 and 65). It is, however, attacked by molten alkali metals, elemental fluorine, and pure oxygen at elevated temperatures, it can also react under some conditions with alkaline earth oxides and finely divided metals such as aluminum or magnesium at elevated temperature. Sorption of solvents is mentioned in Note 13. Solutions containing 0.1–2% PTFE were obtained in perfluorokerosene $C_{21}F_{44}$(FCX-412) in the temperature range 290–310°C (see Refs. 71 and 74).
19. Clear evidence for a crystalline transition at about 90°C is presented in a series of papers by Araki, Refs. 3–5. He also presents evidence for doublets in the transitions Ref. 4, and points out that the alpha and gamma transitions follow the so called 2/3 (Trouton) rule when compared with the first order crystalline transitions at 19 and 327°C, Ref. 3. See also evidence for a doublet in the freezing-point plot shown in Ref. 65.
20. Data on the kinetics of the transitions not amenable to presentation in tabular form are available in Ref. 57.
21. Incorporation of finely divided fillers decreases wear factor by as much as 500 to 1000 fold (Ref. 46).
22. No change in appearance or properties has been observed after more than twenty years exposure in Florida (see Ref. 21).

C. PHYSICAL CONSTANTS OF MELT PROCESSIBLE FLUOROCARBON POLYMERS PFA AND FEP

PFA: $-[(CF_2CF_2)_n(CF_2\underset{OR_F}{CF})]_m-$

FEP: $-[(CF_2CF_2)_n(CF_2\underset{CF_3}{CF})]_m-$

Unlike poly(tetrafluoroethylene), copolymers of tetrafluoroethylene with perfluoro comonomers are made as relatively low molecular weight (i.e., low melt viscosity) products that can be processed by conventional melt procedures and still have properties in the solid state that are similar or superior to those of poly(tetrafluoroethylene). Both PFA, poly[tetrafluoroethylene-*co*-perfluoro(alkoxy vinyl ether)], and FEP, poly(tetrafluoroethylene-*co*-hexafluoropropylene), are included in this table. Various perfluoro(alkoxy vinyl ethers) can be used for PFA. It has been reported that one often used is perfluoro(propylvinyl ether) (14).

Data available for PFA and FEP are not as extensive as for PTFE. In many respects, however, the properties of solid FEP and, especially, PFA, are very similar to those of PTFE. The values given in the table for PTFE, therefore, can often provide useful guidance for the properties of non-molten PFA or FEP for which no values are included in this table.

NOTES

1. Comments on ASTM and ISO standards for fluoropolymers are in Note 2 for the table on PTFE.
2. The values are estimated based on high-spot work on degradation of the polymers.
3. The exact value depends on the type or grade of polymer that is being used.
4. PFA and FEP are insoluble in all common solvents and are highly resistant to essentially all common chemicals (see Ref. 1, 2, and 15). They are however, attacked by molten alkali metals, elemental fluorine, and pure oxygen at elevated temperatures. Also, they can react, under some conditions, with alkaline earth oxides and finely divided metals such as aluminum or magnesium at elevated temperature. Solutions containing 0.1 to 2% FEP were obtained in perfluorokerosene

$C_{21}F_{44}$ (FCX-412) in the temperature range 290–310°C.

5. Determined by 3.0 × IR Ratio. The IR ratio is the absorbance at 980 cm^{-1} (10.2 μm)/absorbance at 2350 cm^{-1} (4.23 μm) (see Ref. 1, 2).
6. Thickness is from 0.025 to 2.5 mm. The value decreases with increasing thickness.
7. No carbon track is formed (see Ref. 7).
8. This numerical rating for flame spread is not intended to reflect hazards presented by this or any other material under actual fire conditions.
9. The MIT flex test is run with a thickness of 0.254 mm.
10. Calculated from data in Ref. 6. The melt flow rate was determined using standard conditions at 372°C.
11. Ref. 3 gives melting temperature, T_m, as a function of wt.% comonomer, X, and lamellar thickness, L. The equation is

$$1/T_m = 1.622 \times 10^{-3} + 2.52 \times 10^{-3}X(1+X) + (1.92 \times 10^{-10}/L)$$

12. The rate of increase of the melting point decreases with increasing pressure.
13. Inconsistencies in the results from various laboratories on heat of fusion of PTFE and FEP have not yet been resolved. This value is for a sample of FEP with a density of 2.148 Mg/m^3.
14. Moderate crosslinking can occur to offset degradation (see Ref. 15).
15. Mechanical properties of PFA at elevated temperature but below its melting point generally are superior to those of PTFE at the same temperature.
16. Calculated from data in Ref. 9.

D. PHYSICAL CONSTANTS OF MODIFIED POLY(ETHYLENE-*co*-TETRAFLUOROETHYLENE) $-[CH_2-CH_2-CF_2-CF_2]-$

Commercially useful copolymers of ethylene and tetrafluoroethylene became feasible when it was discovered that the use of a small amount of a modifier, often a termonomer, resulted in polymers with properties suitable for long term use (Ref. 7). One key requirement, for example, is the ability to withstand exposure at high temperature without rapid embrittlement. The amount of modifier is very low and the exact amount

Notes page V-48; References page V-48

and nature of a modifier has been kept proprietary by each manufacturer, and may be different for different grades within a product line.

The commercial modified poly (ETFE) materials are essentially alternating copolymers (Ref. 10). In molecular formula, they are isomeric with poly(vinylidene fluoride)(PVDF), and can be considered equivalent to a PVDF that has a head to head, tail to tail structure. Many important physical properties of modified ETFE copolymers, however, are very different from and superior to those of available PVDF materials. (These properties do not include the remarkable piezoelectric and pyroelectric performance of PVDF.)

NOTES

1. See additional comments in Note 2 for the table on PTFE.
2. Extensive tables with data on the resistance to a wide variety of chemicals are given in the references.
3. The exact value depends on the particular type or grade of polymer that is being used.
4. Tested at 13.8 MPa and 50°C.
5. The value decreases with increasing thickness.
6. This numerical rating for flame spread is not intended to reflect hazards presented by this or any other material under actual fire conditions.
7. The film tested is 0.25 mm thick.
8. In dibutyl adipate at 250°C.
9. Poly(ETFE) can be crosslinked by ionizing radiation.
10. The exact value depends on the particular type or grade of resin used as well as the method used to prepare the test specimen.
11. The unit cell is believed to be either orthorhombic or orthoclinic.
12. Wear factor is decreased to 16×10^{10} by use of glass fiber filled polymer.

E. PHYSICAL CONSTANTS OF POLY(VINYLIDENE FLUORIDE) $-(CH_2CF_2)-$

Poly(vinylidene fluoride), PVDF, has been used since the early 1960s because of its chemical resistance combined with very good mechanical properties. In addition, it is now known that PVDF has very unusual and valuable piezoelectric and pyroelectric properties (see Ref. 12).

NOTES

1. Comments on ASTM and ISO standards for fluoropolymers are in Note 2 for the table on PTFE.
2. PVDF is resistant to most inorganic and organic chemicals at room temperature. It is, however, especially sensitive to attack by amines (Ref. 3). References (6), (14), and (15) have many pages of tables with information on the specific effect of different chemicals.
3. Many of the useful properties of PVDF stem from its existence in various conformations. The topic is not amenable for detailed presentation in tabular form, but it is discussed in depth in Ref. (12).
4. The value decreases with increasing thickness of the specimen being tested.
5. This numerical rating for flame spread is not intended to reflect hazards presented by this or any other material under actual fire conditions.
6. The exact value depends on the particular type or grade of resin used as well as the details used to make the test specimen.
7. Each conformation has its characteristic infrared spectra. See Ref. (9) for a general spectra and Ref. (12) for a discussion and references to the extensive literature.
8. Good solvents are dimethyl acetamide, dimethyl formamide, hexamethyl phosphoramide, and dimethyl sulfoxide. Some highly polar solvents such as ketones and ethers, are absorbed.
9. PVDF can be crosslinked by ionizing radiation resulting in an increase in high temperature modulus and very little degradation.
10. Calculated from data in Ref. (12) at page 200.
11. Reference (14) has 23 pages of Tables with information on the effect of many different chemicals.
12. Reference (11) has extensive tables for PVDF at temperatures from 10 to 340 K.

F. PHYSICAL CONSTANTS OF AMORPHOUS FLUOROPOLYMERS

Two major families of amorphous fluoropolymers have been developed. Both rely on in-chain rings to reduce crystallinity in the homopolymer and in copolymers with α-olefins such as tetrafluoroethylene and chlorotrifluoroethylene. One incorporates 2,2-bis-trifluoromethyl-4,5-difluoro-1,3-dioxole (PDD) in copolymers with tetrafluoroethylene or chlorotrifluoroethylene (TEFLON® AF) and the other is based on monomers such as 5-oxaperfluoro-1,6-heptadiene, which when polymerized, produce the structure below (CYTOP®). Amorphous fluoropolymers are soluble in a variety of fluorinated solvents and can be cast into thin films as well as conventionally melt processed. Optical properties are a significant market utility. Cost is a major consideration, however, compared to crystalline fluoropolymers.

NOTES

1. See Refs. (2,3) for data on chemical resistance and physical property performance in various solvents.
2. See Ref. (15) for types of solvents and degree of solubility of amorphous fluoropolymers.
3. See Ref. (8) for optical transparency data.
4. Brewster $= 10^{-13}\,cm^2/dyn$.
5. See Ref. (10) for infrared spectral interpretation.
6. Abbe Number = (refractive index at sodium D line minus 1)/(refractive index at hydrogen F line minus refractive index at hydrogen C line).
7. centiBarrier $= 10^{-8} \times (cm^3(STP)\ cm/s/cm\ Hg/cm^2$.
8. T_g of 2,2-bis(trifluoromethyl)-4,5-difluoro-1,3-dioxole homopolymer is 330°C. Glass transition temperature is a strong function of comonomer content.
9. See Ref. (5) for a discussion of radiation effects on optical and physical properties.
10. See Ref. (12) for charge storage data of amorphous fluoropolymers.

G. PHYSICAL CONSTANTS OF POLY(CHLOROTRIFLUOROETHYLENE)

Poly(chlorotrifluoroethylene) (PCTFE) was the first of the fluoropolymers to be made (Ref. 3). It was not until the work of W. T. Miller and his colleagues during the research for the Manhattan (atom bomb) project (Ref. 8), however, that materials with molecular weight suitable for plastics applications became available.

NOTES

1. Comments on ASTM and ISO standards for fluoropolymers are in Note 2 for the table on PTFE.
2. PCTFE is resistant to most inorganic and organic chemicals at room temperature and to most inorganic chemicals such as strong oxidizing agents over a wide range of temperature. It is especially useful in liquid oxygen service. References (4), (6), and (10) have many pages of tables with information on the specific effect of different chemicals.
3. The value is the stress at 0.3% deformation after 24 h.
4. The value decreases with increasing thickness of the test specimen.
5. This numerical rating for flame spread is not intended to reflect hazards presented by this or any other material under actual fire conditions.
6. The exact value depends on the particular type or grade of resin used.
7. The value increases with increasing crystallinity.
8. ZST is a measure of relative molecular weight of PCTFE.
9. PCTFE is noteworthy for its very low permeability.
10. PCTFE generally maintains properties when exposed up to about 18 Mrad of ionizing radiation. Further improvement in resistance can be obtained by incorporating small concentrations of vinylidene fluoride during polymerization.
11. Soluble at 100°C in 2,5-dichlorobenzotrifluoride. Another solvent is 1,2,3,4-tetrafluorohexachlorobutane.
12. The degradation involves random scission rather than "unzippering".
13. Specimens were 80% crystalline.
14. For amorphous polymers.

	153.6	Crystallization from PAN/H_2O – melt under pressure	14
Density (g/cm^3)	1.15–1.18	Sample: flakes and films	12,16,17
	1.17–1.19	Sample: fiber	18
Orientation factor	See Ref.	Sample: stretched films	
		X-ray diffraction studies	
		Chain-orientation factors were measured by IR-dichroism.	15

[a]The reported unit cell dimensions, especially the c-dimension along the chain axis, can only be regarded as estimated because of the diffuse meridian and polar reflections in the X-ray diffraction studies.
[b]The dissolution and crystallization temperatures given here are obtained from a free radical poly(acrylonitrile). They are sensitive to chain irregularities in the polymer. Samples of poly(acrylonitrile) obtained from different sources show marked differences in the dissolution and crystallization temperatures, although they have similar IR-spectra, X-ray diffraction patterns and densities.

TABLE 3. FIBER PROPERTIES

Property		Conventional acrylic fibers (≥ 85% AN)[a] (Refs. 18, 32–36)	PAN-fiber Dralon T (100% AN) (Ref. 35)	High strength acrylic fibers[b] (Refs. 38,39)	Acrylic fibers from isotactic PAN[c] (Ref. 40)
Fiber fineness (dtex)		0.6–19.0	3.3–17.0	1.0–4.0	
Density (g/cm^3)		1.14–1.19	1.17–1.19		
Tenacity [21°C/65% RH] (cN/dtex)		1.8–4.5	3.5–6.0	10–20	8.0–20.0
Tenacity [wet/dry ratio] (%)		75–95	80–100		
Elongation ε [21°C/65% RH] (%)		30–60	25–40	7–10	
Elongation [wet/dry ratio] (%)		100–120	≈ 100		
Initial modulus [(Elongation $\varepsilon \rightarrow 0$)] (cN/dtex)		30–100	95–160	140–270	
Modulus in hot water [90°C] (cN/dtex)		1.0–5.5 (Ref. 37)			15.0–21.0
Relative knot tenacity	(%)	70–90	≈ 70	4.5–6.5 (cN/dtex)	
Relative loop tenacity	(%)	30–80	≈ 60		

[a]The properties of acrylic fibers manufactured by conventional processes of wet or dry spinning are dependent on spinning conditions and the monomer content in the polymer itself. Some trade names of acrylic fibers: Acrilan, Cashmilon, Courtelle, Dolan, Dralon, Euracryl, Leacryl.
[b]Polyacrylonitrile fibers with high tensile strength are prepared under special conditions: Use of polyacrylonitriles with high molecular weight ($\bar{M}_w > 5.0 \times 10^5$ g/mol), wet or dryjet/wet spinning and forming a fiber with a gel structure, afterwards stretching to high degrees (draw ratios 15–30).
[c]Fibers are made from polyacrylonitriles with highly isotactic content (mm > 0.40). They are prepared by anionic polymerization with a special catalyst.

TABLE 4. FURTHER PROPERTIES OF ACRYLIC FIBERS

Property	Value[a]	Remarks	Refs.
Elastic recovery [(1-$\varepsilon_r/\varepsilon$) × 100] (%)		*Effects of acids and alkalis*	36,42
ε = 2.0%	90–95	Good to excellent resistance to mineral acids,	
ε = 5.0%	50–90	fair to good resistance to weak alkali, and	
		moderate resistance to strong cold solutions of alkali	
Torsion modulus (cN/dtex)	10–17		
Fiber shrinkage [in water, 95°C] (%)		*Effects of bleaches and solvents*	
Drawn fiber	14–22	Good resistance to strong bleaches and common solvents;	
Thermoset fiber	≈ 1.0	Unaffected by dry cleaning solvents;	
Water absorption [(21°C/65% RH)] (%)	1.0–1.5	Can be bleached with sodium chlorite	
Water retention (%)	4.0–12.0[b]	*Resistance to mildew, aging, sunlight, abrasion*	41
Glass transition temperature (°C)		Not attacked by mildew;	
Dry	85–95	Good resistance to aging, sunlight and abrasion	
Wet	50–60		
Melting/decomposition temperature (°C)	250–320		
Heat resistance in air (°C)	140		
Fire limiting oxygen index (LOI) (°C)	18

† Tacticity of PAN was determined by ^{1}H-NMR, ^{2}H-NMR and ^{13}C-NMR, computing the spectra, and by decoupling techniques.

Property	Value	Remarks	Ref.
Spectral data[a]			
Nuclear magnetic resonance spectrum			
^{1}H-NMR, ^{2}H-NMR	See Refs.	Configuration of PAN	54–58
^{13}C-NMR	See Refs.	Stereoregularity of PAN	48,53,59–61
Solid-state NMR	See Refs.	Chain conformation and phase structure of PAN	62–64
Infrared spectrum	See Refs.		65–72

[a] Stereoregularity and spectral data were properly provided with separate generic terms..

TABLE 7. SOLUBILITY/SOLUTION PROPERTIES

Property	Value	Remarks	Refs.
Solvents	Dimethylformamide, dimethyl sulfoxide, dimethylacetamide, ethylene carbonate, propylene carbonate, malononitrile, succinonitrile, adiponitrile, γ-butyrolactone, conc. sulfuric and nitric acid, conc. salt solutions: LiBr, NaCNS, $ZnCl_2$;	See also corresponding chapter of this Handbook Solvents and Nonsolvents	73,74
Solubility			
Hildebrand parameter δ_2 $[J/cm^3]^{1/2}$	31.5 (exp.); ~26.0 (estim.) See also corresponding chapter of this Handbook	Estimated values from empirical formulae of Hildebrand/Scott and Askadskii	75
Dissolution of highly isotactic PAN	See Ref.	Solution temperature as function of isotacticity and molecular weight	76
Intrinsic viscosity (η)			77,78
Solvent dependence	See Ref.	Data and factors which convert $[\eta]$-values from one solvent into another	79

Property	Value	Remarks	Ref.
Temperature dependence	See table		

Solvent	T (°C)	Huggins' coefficients	$-(d \ln[\eta]/dT)$
N,N-Dimethyl-formamide	25 35	34 33	0.14–0.19
N,N-Dimethylacetamide			0.27
Dimethyl sulfoxide			0.08
60% HNO_3			0.05
γ-Butyrolactone			0.14 0.13–0.17
Hydroxyacetonitrile acetonitrile			0.07

Property	Value	Remarks	Ref.
Viscosity–molecular weight relationship	See corresponding chapter in this Handbook	Mark–Houwink–Sakurada equation	
Dilute solution properties			
Unperturbed dimensions of linear chain molecules	See corresponding chapter in this Handbook		
Partial specific volume	See corresponding chapter in this Handbook		
Huggins and Schulz–Blaschke coefficients		See corresponding chapter in this Handbook	
Sedimentation and diffusion coefficients	See corresponding chapter in this Handbook		
Parameters of isotactic PAN	See Ref.	Effects of stereoregularity on Mark–Houwink–Sakurada equation for different solvents, further on the radius of gyration $\langle S^2 \rangle$, the second virial coefficient A_2 and the conformation parameter	80
Parameters of ultrahigh molecular weight PAN	See Ref.	Dependence of molecular weight on radius of gyration $\langle S^2 \rangle$, second virial coefficient A_2 and intrinsic viscosity $[\eta]$	81
Viscosity and related parameters	See Ref.	η-values, activation parameters of viscous flow, voluminosity and shape factor at different temperatures (Solvent: DMF)	82
Flexibility parameter (λ) (Theta conditions)	7.20–7.68	Solvent: DMF λ is defined by Kratky–Porod for random-coiled polymers	83
Dissolution temperature[a] (°C)	125–130	In propylene carbonate	12,13

[a] The dissolution and crystallization temperatures given here are obtained from a free radical poly(acrylonitrile). They are sensitive to chain irregularities in the polymer. Samples of poly(acrylonitrile) obtained from different sources show marked differences in the dissolution and crystallization temperatures, although they have similar IR-spectra, X-ray diffraction patterns and densities.

TABLE 8. SPECIAL SOLID STATE PROPERTIES

Property	Value	Remarks	Refs.
Gas permeability (P) $\left[\frac{g \times cm}{cm^2 \times s \times bar}\right]$			
O_2 (film, 25°C) (film, 25°C/65% RH)	2.15×10^{-15} $150–195 \times 10^{-15}$	Relationship between published and CGS permeability units	84,85,86
CO_2 (film, 25°C)	11.8×10^{-15}	$1 \frac{g \times cm}{s \times cm^2 \times bar} = \frac{298.82}{M} \frac{cm^3(STP) \times cm}{s \times cm^2 \times cmHg}$	
H_2O (film, 25°C)	18.4×10^{-10}	Where M is the molecular weight of the penetrant gas	
Polymer surface energy δ (m N/m)	58.8 49.9/54.1	Calculated from cohesion parameters and refractometric data	87 88
Critical surface tension γ_c (dyn/cm)	See corresponding chapter of this Handbook		
Vickers microhardness H_V (kg/mm^2)	11–24	H_V is a function of load L ($L = 20–60$ g) Sample: film	89

References page V / 64

TABLE 9. THERMAL AND THERMODYNAMIC DATA

Property	Value	Remarks	Refs.
Heat capacity C_P Enthalpy function $H_T - H_O$ Entropy function $S_T - S_O$	See table See also corresponding chapter of this Handbook	C_P-data based on measurements in the solid state Enthalpy and entropy functions are calculated	90

T (K)	C_P (J/mol/K)	$H_T - H_O$ (J/mol)	$S_T - S_O$ (J/mol/K)
50	13.77	244.7	7.546
100	30.23	1388	22.73
150	40.44	3167	37.02
200	49.77	5410	49.87
250	58.48	8101	61.84
300	68.84	11277	73.40
350	80.83	15012	84.89
370	86.18	16681	89.53

Property	Value	Remarks	Refs.
Heat capacity C_P ($T > T_g$)	See Ref.	Calculated heat capacity data for states above the Glass transition temperature	91
Specific heat of combustion Δh_c (KJ/g)	30.6 (expt.) 31.5 (calc.)	Δh_c is related to other parameters, such as oxygen index and char residue	92
Thermal decomposition temperature[a] (°C)	250–310		33
Initial decomposition temperature (°C)	248		
Exotherm decomposition range (°C)	238–299	Data from DSC and thermogravimetry analysis	93
Heat of oligomerization ΔH (J/g)	530.9		
	See Ref.	Ranges of decomposition and activation energies for the thermal degradation in air and nitrogen	94
Thermal decomposition activation energies and products	See also corresponding chapter of this Handbook		
Glass transition temperature T_g (°C)	85–104	Various data cited in the 3/e of Polymer Handbook	95
	110	Sample: film Method: fluorescence probe technique	96
	65/105	Existence of two transition temperatures in thermomechanical analysis	97
	See Ref.	Effects of solvents and thermal treatment on T_g	97
	See Ref.	Chain-length dependence of T_g	98
	See also corresponding chapter of this Handbook		
Melting point T_m (°C)	~320	Normally PAN decomposes before melting	99,100
T_m (H_2O) (°C)	184.7	Melting temperature in the wet state under self generated pressure	14
	See also corresponding chapter of this Handbook		
Thermal conductivity κ (mW/cm/K)	0.022 (5 K) 0.440 (20 K) 1.600 (100 K)	Sample: discs from powder	101
Coefficient of expansion (K^{-1})			
Volume (1/V) × $(dV/dT)_P$	2.8×10^{-4}–3.8×10^{-4} (above T_g) 1.4×10^{-4}–1.6×10^{-4} (below T_g)		45,102,103
Linear (1/V) × $(dV/dT)_P$	1.6×10^{-4}–2.0×10^{-4} (above T_g) 1.0×10^{-4} (below T_g)		104,105

[a]The thermal decomposition temperature determined by thermogravimetric analysis ranges from 250°C for a PAN-sample prepared with an ionic catalyst, to 310°C for a commercial fiber. Pyrolysis of poly(acrylonitrile) carried out in the absence of oxygen at 500–800°C yields HCN and low molecular weight nitriles such as monomer, dimer and methacrylonitrile leaving a residue with a condensed ring structure.

Branching

Branching Content (Branches per 1000 Monomer Units (C_2)) as a Function of Polymerization Temperature

T_{polym} (°C)	-CH- | CH_2Cl	-CCl- | CH_2CH_2Cl	-CCl- | $CH_2CHClCH_2CH_2Cl$	H/Cl | -C-C-C- | C	Refs.
45	3.9	< 0.1	0.5	< 0.1	1[a]
55	4.2	0.2	0.6	0.2	1[a]
65	4.6	0.2	0.8	0.3	1[a]
80	4.9	0.3	1.3	0.3	1[a]
100	5.0	1.4	2.1	0.8	2[b]

All data from ^{13}C-NMR.
[a]Extrapolated to 0 subsaturation, reduced with Bu_3Sn as per Ref. 3.
[b]Reduced with Bu_3Sn as per Ref. 4.

Brittle to Ductile Transition Pressure (kbar) Value of 0.2 kbar, measured under tensile deformation of 10% per minute at 25°C. (5)

Coefficient of Thermal Expansion (K^{-1})

$< T_g$ before annealing, 6.6–7.3 × 10^{-5} (6)
after annealing, 6.9 × 10^{-5}
$>T_g$ 17.0–17.5 × 10^{-5}
With plasticizer. (7)

Coefficient of Friction

PVC on Steel (8)

Plasticizer[a] (%)	Static	Dynamic
25.9	0.350	0.719
31	0.495	0.787
35.5	0.645	0.857
39.4	0.797	0.925

[a]Di-2-ethylhexyl phthalate (DOP), di-iso-decyl phthalate (DIDP), *n*-octyl-*n*-decyl phthalate (DNODP). A value of 0.45–60 for unplasticized PVC with steel has been reported (9). For further data see Ref. (10).

Compressibility (MPa^{-1}) (×10^6) (11)

Uniaxially Stretched PVC

Elongation (%)	$\gamma_{\parallel}$	$\gamma_{\perp}$
85	4.88	8.0
125	4.25	8.45
160	3.57	8.75

See also Refs. 12,13, and 36.

Creep (14,15)

Crystallinity (%)
From Density Measurements (16)

T_{polym} (°C)	Crystallinity (%)
90	11.3[a]
55–60	11.3
50	13.2
20	15.0
−15	57.3
−75	84.2

[a]Assumes amorphous density equals 1.385 g/cm^3 and crystalline density equals 1.44 g/cm^3 (19). Since the crystalline density for highly crystalline (e.g., single crystal) PVC is considerably greater than 1.44 g/cm^3; as shown in the table on crystallographic data, the above % crystallinity values for the low temperature polymerized PVCs are greatly overestimated. As pointed out by Kostyuchenko and co-workers (20), if a crystalline density of 1.497 g/cm^3 or greater is used, the calculated percent crystallinity values agree better with X-ray diffraction measurements.

Crystallinity cont'd
From X-Ray Diffraction Measurements

T_{polym} (°C)	Crystallinity[a] (%) (17)	T_{polym}	Crystallinity[b] (%) (18,40)
90 frac. 1	10.4	50	13[c]
frac. 3	5.4	− 20	17
53 frac. 1	10.4	− 40	20.5,20
A	6.5	− 60	23,25
B	8.2		
25	12.2	polym. in propionaldehyde	33[c]
− 60	23.7		
	34.7[c]	polym. in *n*-butyraldehyde	

[a] Values obtained using the X-ray diffraction method of Hermans and Weidinger (21) and a double hump amorphous curve.
[b] X-ray diffraction method with Lorentz-polarization and atomic scattering factor corrections.
[c] Using a single hump amorphous X-ray curve and the method of Hermans and Weidinger (21), Lebedev and co-workers (22) (see also Ref. 17) report several commercial PVC crystallinites in the range 20–27%. In general, their method gives higher values than that of D'Amato and Strella (17).

From IR Measurements
Crystallinity from IR measurements deemed (by the authors) to be less accurate than NMR are in references 42, 44–46 and 56.

From Calorimetric Measurements (Unfractionated Polymers) (23)

M_n	T_{polym} (°C)	Crystallinity (%)
23,200	75	18.4
38,700	65	15.5
53,500	52	15.3
66,700	52	14.4
136,000	25	11.9
155,000	25	11.8

Crystallographic Data See under Unit Cell.

Density (g/cm^3)
Function of Polymerization Temperatures (16)

T_{polym} (°C)	M_n	Density (20°C)
90	23,750	1.391

[a]Storage, G', and Loss, G'', are in Pascal. Data from L. A. Utracki, SPE Techn. Papers **31**, 1024 (1985); J. Vinyl. Technol. **7** (4), 150 (1985). M_w of PVC tested is 90.700 (GPC in THF), LVN 30°C in 93 ml/g cyclohexanone.

Specific Refractive Index Increment See corresponding chapter in this Handbook.

Specific Volume
As a function of temperature and pressure. (29)

Spectral Data
a. Infrared absorption bands. (123)
b. Nuclear magnetic resonance (high resolution spectra). (124–126)
c. Carbon-13 magnetic resonance (chemical shift assignment) (127–129)

Stress Optical Coefficient (soc)
−200 to +50 −6.5 (132,133)

The value of the SOC becomes positive at T_g, but there is some arbitrariness associated with it because above T_g the plots of birefringence change with stress and have an S shape.

Tacticity (Fraction of syndiotactic dyads)
Dependence on Polymerization Temperature[a]

T_{polym} (°C)	Tacticity[b]	Refs.
55	0.55	130
50	0.55[c]	129
25	0.57	130
0	0.60	130
−30	0.64	130
−50	0.66	130
−76	0.68	130

[a]Data based on ^{13}C NMR measurements.
[b]High tacticity data may be low due to insolubility during measurement as discussed in Ref. 131.
[c]Bernoullian order.

Tensile Modulus (MPa) = (N/mm^2)

T (°C)	Value	Refs.
−196°C	7584	137[a]
−120°C	5171	137
−75°C	3861	137
20°C	2964	137
30°C	3000	14[b]
40°C	2930	14
50°C	2427	14
60°C	1551	14
70°C	276	14

[a]Stress–Strain measurements at strain rate of 0.00250 s^{-1}.
[b]Measured in creep (100 s, 0.2% strain).

Thermal Conductivity (W/m/K) (138,140)

T (°C)	Thermal conductivity
−170	0.129
−150	0.134
−125	0.139
−100	0.144

60	0.164
70	0.164
80	0.165
90	0.165
100	0.165

Thermal conductivity of system PVC/di-2-ethylhexyl phthalte (see Ref. 139).

Molecular weight, sample polymerization temperature and syndiotactivity do not influence the thermal conductivity of polymers appreciably, except in the case where tacticity leads to crystallization.

Thermal Diffusivity (140)

T (K)	Density (g/cm^3)	Thermal diffusivity (×10^{-4}) (cm^2/s)
200	1.417	14.40
220	1.415	13.95

400	1.306	7.30
420	–	7.13
440	–	7.04
460	–	6.99
480	–	7.06

Unit Cell

PVC sample type	Crystal system	Space group	Unit cell parameters (Å) a	b	c	Monomers per unit cell	Calc. density (g/cm^3)	Refs.
Commercial, polymerized at 50–60°C	Orthorhombic	Pacm	10.6	5.40	5.10	2	1.44	19
Solution blended high molecular weight, low crystallinity commercial polymer and low molecular weight, high crystallinity polymer	Orthorhombic	Pacm	10.4	5.30	5.10	2	1.48	141
Single crystals, polymerized at −75°C	Orthorhombic		10.32[a]	5.32[a]	–	–	(1.49)[b]	142
Single crystals, low molecular weight, polymer made in *n*-butyraldehyde	Orthorhombic	Pacm	10.24	5.24	5.08	2	1.53	143

[a]Calculated from published *d*-spacings of major diffraction peaks.
[b]Calculated density assuming $c = 5.10$ (Å) and 2 monomers per unit cell.

Unperturbed Dimensions See corresponding chapter in this Handbook.

Viscosity–Molecular Weight Relationship See Intrinsic Viscosity.

Zero Shear Viscosity (34)

APPENDIX 1: APPARENT MELT VISCOSITY OF UNMODIFIED PVC[a] PREPARED AT VARIOUS POLYMERIZATION TEMPERATURES[b] (PAS) ($\times 10^4$)

[a]Ref. original data, E. A. Collins, unpublished.
[b]Melt viscosity data obtained using a capillary having a 90° entrance angle, length 1.0 in and diameter 0.05 in. No correction applied to the data. All samples contained 2.5 parts dibutyltin dioctylthioglycolate stabilizer per 100 parts resin.
[c]Limiting viscosity number, determined in cyclohexanone 30°C.
[d]Modified with 5 parts trichloroethylene/100 parts vinyl chloride monomer.
[e]Modified with 3 parts trichloroethylene/100 parts vinyl chloride monomer.

Physical Constants of Poly(vinyl acetate)

M. K. Lindemann
Consultant, Greenville, SC, USA

Property	Value	Remarks	Refs.
Absorption of Water (%)	Approx. 3–6	At 20°C for 24 to 144 h	26
	4	At 23°C	65,66
	6	At 70°C	
Adhesive Strength			
Lap shear (Mpa)	3.9	Aluminum	130
Peel strength (N/cm)	1.9	Aluminum	
Chain Dimensions and Entanglement Spacings	See Refs.		144–146
Cohesive Energy (J/mol)	26000–36000		52
Cohesive Energy Density (J/cm^3)	3.69×10^2		58
Compressibility ($cm^3/g/atm$)	1.8×10^{-5}	In the glassy state	1
Isothermal (bar^{-1}) ($\times 10^{-5}$)			
At 80°C	6.2		113
At 100°C	6.6		
At 120°C	7.1		
Decomposition Temperature (°C)	150		15
Degradation, Thermal	$T^{1/2} = 269°C$; $E_{act} = 71$ kJ/mol; monomer yield: none	Temperature at which the polymer loses 50% of its weight, if heated in vacuum for 30 min	52
Density (Mg/m^3) $\equiv$ (g/cm^3)			
At 20°C	1.191		16,24,26
At 25°C	1.19		
At 50°C	1.17		
At 120°C	1.11		
At 200°C	1.05		
At the melting point	1.28		58
At $T = 35$–$100°C$	$1.2124 - 8.62 \times 10^{-4}\, T + 0.223 \times 10^{-6}\, T^2$		113
At $T = -30$ to $+20°C$	$1.196 - 3.37 \times 10^{-4}\, T$		113
As a function of pressure	See Refs.		113,114,115
Dielectric Constant	3.5	At 50°C and 2×10^3 kHz	34
	8.3	At 150°C and 2×10^3 kHz	
Of oligo PVAC	See Ref.		59
As a function of MW	See Ref.		96
Dielectric Dissipation Factor ($\tan \delta$)	1.5×10^2	At 50°C and 2×10^3 kHz	34
	26×10^2	At 120°C and 2×10^3 kHz	
Dielectric Loss Versus Frequency	See Ref.	At various temperatures	95
Dielectric Strength (V/cm) ($\times 10^{-3}$)	394	At 30°C	16
	307	At 60°C	

Property	Value	Remarks	Refs.
Dielectric Relaxation Parameters	See Refs.		121–129
Dipole Moment (ESU (per monomer unit))	2.3×10^{-18}	At 20°C	22,23
	1.77×10^{-18}	At 150°C	
(debye units)	4.8 D	For oligo PVAC, $n = 5$	59
Dynamic Mechanical Loss Peak (°C)	70	At 100 Hz	33
Elongation At Break (%)	10–20	At 20°C, %RH	27
Gas Diffusivity	See Ref.	For N_2, O_2, CO_2, H_2	52
Gas Permeability	See Refs.	Diffusion and sorption of CO_2 (below and above T_g)	53,94
N_2 for PVAC below T_g(cm^2/s/bar)	6×10^{-10}		52
N_2 for PVAC above T_g	5×10^{-10}		
O_2, 73°dry film	2.7×10^{-9}		100
Gas Solubility (cm^3(STP)/cm^3 bar)	N_2 0.02	At 298 K	52
	O_2 0.04		
	H_2 0.023		
Gel Permeation Chromatography	See Refs.	Universal calibration	90,91,92
Gel Properties			
Swelling pressure, elastic modulus and shear modulus parameters of PVAC networks in toluene and acetone	See Ref.		166
Glass Transition Temperature (°C)	28–31		25
	25.8	Isotactic PVAC $M_n \sim 10^5$	63
	31.4	Atactic PVAC $M_n \sim 1.66 \times 10^5$	
	23.6	Atactic PVAC $M_n \sim 3922$	
	34–39	Dry	65
	<30	Wet	
	11	PVAC containing 4.20% water	66
Pressure dependence (K/bar)	0.022		18
As a function of MW	See Refs.		62,64
Activation energy for the glass transition (J/mol)	$\Delta H_a = 1.8 \times 10^5$		60
Hardness (Shore units)	L 80–85	At 20°C	27
Heat Capacity (kJ/kg)	1.465	At 30°C	21
	$C_{p(liquid)} = 1.77$	At $T_g = 304$ K	67
	$C_{p(glass)} = 1.27$		
	0.116	$\Delta C_p = C_{p(liquid)} - C_{p(glass)}$	68
	$C_{v(liquid)} = 1.51$	At $T_g = 304$ K	
	$C_{v(glass)} = 1.20$		
At $T = 320$ K	$C_{p(liquid)} = 1.8409$ (kJ/kg); 158.48 (J/mol/K)		14,147
At $T = 370$ K	$C_{p(liquid)} = 1.898$ (kJ/kg); 163.37 (J/mol/K)		
At $T = 80$ K	$C_{p(glass)} = 0.323$ (kJ/kg); 27.81 (J/mol/K); 53.7 (ΔC_p, J/mol/K)		
At $T = 300$ K	$C_{p(glass)} = 1.183$ (kJ/kg); 101.86(J/mol/K)		
Heat Conductivity (J/s/m/K)	0.159		52
Heat Distortion Point (°C)	50		16
Heat of Polymerization (kJ/mol)	87.5		31,32
Index of Refraction (n_D)			28
At 20°C	1.5013	At 6563 Å	104,105
At 20°C	1.5100	At 4861 Å	
At 20°C	1.5174		
At 20°C, medium acetate type	1.4903		
At 20°C, low acetate type	1.523–1.57		

Property	Value	Remarks	Refs.
At 20°C, molding compound	1.4685		
At 20.7°C	1.4669		
At 30.8°C	1.4657		
At 52.1°C	1.4600		
At 52.1°C	1.4600

Physical Constants of Poly(methyl methacrylate)*

W. Wunderlich
RÖHM GmbH, Darmstadt, FR Germany

Property	Value	Remarks	Refs.
Birefringence $(\alpha_1 - \alpha_2)$ (cm^3)			
Segmental anisotropy	2×10^{-25}	Benzene	1
	20×10^{-25}	Benzene, isotactic	
Ceiling Temperature (K)	478		47
Coefficient of Thermal Expansion (K^{-1})			
Linear	7×10^{-5}	0–50°C	2
Volume	2.60×10^{-4}	$<T_g$	3
	2.55×10^{-4}	$<T_g$	4
	2.72×10^{-4}	$<T_g$	5
	2.25×10^{-4}	$<T_g$	6
	5.80×10^{-4}	$>T_g$	3
	5.60×10^{-4}	$>T_g$	4
	5.80×10^{-4}	$>T_g$	5
	5.75×10^{-4}	$>T_g$	6
Compressibility (MPa^{-1}) ($\times10^6$)			
	245	$T = 20°C$	7
	290	60°C	7
	355	100°C	7
	390	109.3°C	7
	500	119.8°C	7
	530	129.7°C	7
	561	150°C	8
	644	200°C	8
Density (mg/m^3) ≡ (g/cm^3)	1.195	0°C	9
	1.190	20°C	10
	1.188	25°C	11
	1.150	T_g	12
Diffusion O_2 in PMMA (cm^2/s) ($\times 10^8$)	0.5	0.21 bar, 25°C	13
	1.0	0.4 bar, 25°C	13
	1.4	1 bar, 25°C	13
	3.8	1 bar, 20°C	14
H_2O in PMMA (g cm/cm^2/h)	5.2	Permeability	15
Dielectric Constant	3.6	50 Hz, 25°C	16
	3.0	1 KHz, 25°C	16
	2.6	1 MHz, 25°C	16
	2.57	30 GHz, 25°C	17,18
	2.59	138 GHz, 25°C	18
Dissipation Factor (tan δ)	0.062	50 Hz, 25°C	16
	0.055	1 KHz, 25°C	16
	0.014	1 MHz, 25°C	16
	0.007	30 GHz, 25°C	17,18
	0.010	138 GHz, 25°C	18
Elongation at Break (%)	4	$10^5 \leq M_w \leq 2\times10^5$	48
	5.5	$2\times10^6 \leq M_w$	48

*Data are valid for normal radical polymerized PMMA if no tacticities are given.

Physical Constants of Poly(styrene)

David Schrader
Designed Thermoplastics Research, The Dow Chemical Company, Midland, MI, USA

Property	Value	Remarks	Refs.
Birefringence Dispersion			
$\frac{\Delta n(\lambda)}{\Delta n\ (546\,\text{nm})}$	$A + B/\lambda^2 + C/\lambda^4$	$A = 0.8905$ $B = 0.275 \times 10^{-9}\,\text{cm}^2$ $C = 0.153 \times 10^{-18}\,\text{cm}^4$	21
Coefficient of Thermal Expansion (K^{-1})			
Linear	$6\text{–}8 \times 10^{-5}$	$<T_g$ (unoriented)	3
Volume	$1.7\text{–}2.1 \times 10^{-4}$	$<T_g$	7a
	$5.1\text{–}6.0 \times 10^{-4}$	$>T_g$	7a
Coefficient of Friction	0.515	20–80°C	7b,7c
	0.744	100°C	7b
	>2	120°C	7b
	0.25	100°C	7c
	2.65	110–120°C	7c
Cohesive Energy Density	See solubility parameter		
Common Solvents	Toluene, perchloroethylene, carbon tetrachloride, carbon disulfide, tetralin, dioxane, MEK, pyridine, cyclohexanone, ethyl acetate		34
Compressibility (MPa^{-1})	220×10^{-6}		3
Compressive Modulus (MPa) ≡ (N/mm^2)	3000	Unoriented	18a
Creep/Stress Relaxation	See Ref.		35

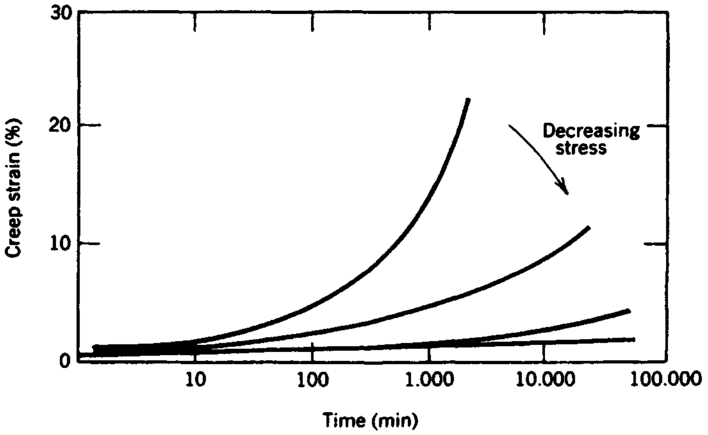

Figure 1. Typical creep behavior for rubber-modified styrene polymers.

Property	Value	Remarks	Refs.
Crystallographic Data	See under Unit Cell		
Density (mg/m^3)			
Amorphous	1.04–1.065		3,4
Crystalline	1.111		2
	1.12		1,5
d_ρ/dT ($g/cm^3/K$)	-2.65×10^{-4}	$<T_g$	6
d_ρ/dT ($g/cm^3/K$)	-6.05×10^{-4}	$>T_g$	6

Property	Value	Remarks	Refs.
Dielectric Constant (ε)			
Amorphous	2.49–2.55	at 1 kHz (curve flat to 1 GHz)	3
Crystalline	2.61	at 1 kHz (curve flat to 1 GHz)	16a
Dissipation Factor			
Amorphous	15×10^{-4}	at 1 kHz (curve flat to 1 GHz)	3
Crystalline	3×10^{-4}	at 1 kHz (curve flat to 1 GHz)	16a
Dynamic Mechanical Loss Peaks			
1 Hz	$T_{\beta} = 300$ K		16b
	$T_{\gamma} = 138$ K		16b
7 kHz	$T_{\delta}^{\gamma} = 48$ K		16c
Entanglement Molecular Weight	19100		43
Glass Transition Temperature, T_g (°C)	80		6
	90	T_g (K) = 373 − $(1.0 \times 10^5/M_v)$	8
	(100)		9
Heat Capacity, C_P (kJ/kg/K)	1.185 (1.139)	0°C	3,12
	1.256 (1.394)	50°C	3,12
	1.838 (1.821)	100°C	3,12
dC_P/dT (kJ/(kg K^2))	4.04×10^{-3}	50°C	3
Heat Capacity vs. Temperature	See Fig. 2		36–37

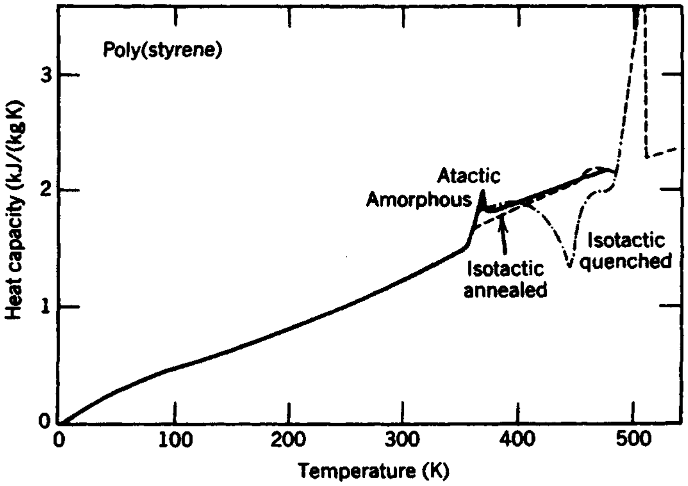

Figure 2. Heat capacity vs. temperature curves for amorphous, atactic, and isotactic poly(styrenes).

Property	Value	Remarks	Refs.
Heat of Combustion (kJ/mol)[a]	-4.33×10^3		13a,14
Heat of Fusion (kJ/mol)[a]	8.37 ± 0.08		10
Crystalline	9.00		2
Heat of Polymerization (kJ/mol)[a]	−67.4	To solid polymer	15
	−69.9	To solid polymer	13a
Heat of Solution (kJ/mol)[a]	−3.60	In monomer	13a
Infrared Spectrum		See Ref.	13b
Intrinsic Viscosity vs. MW	Various solvents	See Ref.	38
Limiting Oxygen Index (%)	18.1		44
Melting Point T_M (°C)	240		10
	(250)		11
Melt Viscosity – Molecular Weight Relationship	$\log \eta_r = 3.4 \log M - k$		

	T (°C)	*M* range	*k*	Refs.
Atactic	217	$\geq 38{,}000$	13.04	31
Isotactic	281	100000–600000	14.42	32a
				39

[a]mol: Monomer unit.

Property	Value	Remarks	Refs.
MW Distribution Curves

Nuclear Magnetic Resonance — **Line width** (gauss)

T (°C)	Value
0	6.7
50	6.5
100	5.0
150	1.0

Property	Value	Remarks	Refs.
	peaks (ppm) at 3.0, 3.5 (aromatic), 8.4 (CH_2)	Referred to tetramethylsilane as + 10.0	32c
Optical Dispersion, $\eta_F - \eta_C$	1.92×10^{-2}	$\lambda = 486.1$ nm	3
		$\lambda = 656.3$ nm	3
Poisson's Ratio	0.325		3
	0.33		20
Refractive Index, n_D	1.59–1.60	$\lambda = 589.3$ nm	3
dn_D/dT (K^{-1})	-1.42×10^{-4}		3
Resistivity (Ohm cm)	10^{20}–10^{22}		17a
Solubility Parameter $(J/m^3)^{1/2} \times 10^{-3}$	16.6–20.2 (8.1–9.9 $(cal/cm^3)^{1/2}$)		40
Sonic velocity (m/s)	2100		3
Specific Gravity	1.04–1.06		41
Stress–Optical Coefficient (brewsters)	10.1	Monofilament	22
	9.5	Extruded sheet	22
	8.3,8.7	Compression molded	22
Stress–Strain Curves	See Figs. 4–6 (next page)		42
Surface tension, 293 K, mN/m (≡ dyn/cm) (Ps/air)	40.7		45
syndiotactic			47
Tensile Modulus, E (MPa) ≡ (N/mm^2)	3200	Unoriented	19
	3400		18a
	4200	Oriented monofilament	18b,18c
dE/dT (N/mm^2/K) ≡ (MPa/K)	−4.48		19
Thermal Conductivity (W/m/K)	0.105	0°C	3
	0.116	50°C	3
	0.128	100°C	3
Thermogravimetric Analysis			17b
In vacuo (10°C min^{-1})			

Wt. loss (%)	*T* (°C)	Wt. loss (%)	*T* (°C)
0	275	40	390
5	330	60	408
10	343	80	422
20	360	100	450

Physical Constants of Poly(oxymethylene)

K.-F. Mück
Ticona, Kelsterbach, FR Germany

Property	Value	Refs.
Absorption		
Homopolymer (density 1.418–1.419 g/cm^3)		
Equilibrium concentration, 60°C		
Aniline (wt.%)	9.60	1
m-Cresol (wt.%)	16.48	1
Dimethylformamide (wt.%)	5.73	1
Water (DIN 53 472, after 96 h), (mg)	20 –30	3
(wt.%)	~0.14–0.21	
Gain in volume, 60°C (vol.%)		
Aniline	13.7	1
m-Cresol	23.0	1
Dimethylformamide	8.6	1
Average sorption coefficient, 25°C		
Water	See Ref.	2
Activation Energy of Polymerization (kJ/mol)		
Of radiation induced trioxane		
In source polymerization	~21; 121	72
Post polymerization >50°C	167	72
<50°C	287	72
44–55°C	126	72
45–55°C	165; 174	72
Of cationic polymerization of trioxane		
In ethylene dichloride	79.5	81
In the solid state	36	81
Anisotropy of Solid State Extruded POM	See Ref.	127
Arc Resistance (s) (ASTM D495)		
Homopolymer	129 (burns)	73
Copolymer	240 (burns)	73
DIN 53484, VDE 0303, part 5		
Copolymer	L4	
Ceiling Temperature (°C)		
Polymerization of formaldehyde (gas) → poly(oxymethylene) (solid)		
At 1 bar	119	66
	127	25
	116	9
	120	22
	137	90
	126	94
	133	95
At different pressures calculated from Ref. 66	(see table below)	67

p (bar)	t_c (°C)
0.36	100
0.62	110
1.06	120
1.75	130
2.81	140
4.44	150
6.85	160
10.36	170

Polymerization of trioxane (gas) → poly(oxymethylene) (solid)	36	94

Property	Value		Refs.
Chemical Resistance	See Refs.		73,79
Coefficient of Linear Thermal Expansion (K^{-1})			
20–100°C (VDE 0304)	$1.0–1.4 \times 10^{-4}$		3
Amorphous > T_g (ASTM D 696)	7.2×10^{-4}		6
Copolymer	0.85×10^{-4}		73
Homopolymer DIN 52328, ASTM 696	0.81×10^{-4}		73
Copolymer	1.1×10^{-4}

Physical Constants of Poly(oxyethylene-oxyterephthaloyl) (Poly(ethylene terephthalate))

Mark Rule
1 Coca Cola Plaza NW, TEC 147, Atlanta, GA, USA

Properties of films are given for Mylar® Type A (DuPont) biaxially oriented and crystalline films. Properties of filaments are given for various products.

Property	Value	Refs.
Birefringence of Filaments (sodium light)*		1
Draw Ratio		
2.0	0.040	
3.0	0.092	
4.0	0.167	
5.0	0.193	
Bursting Strength (g/cm^2)		
1 mil film, 23°C	46×10^2	2,3
Brillouin Light Scattering	See Ref. 4	
Coefficient of Friction (film)		
Kinetic, film to film	0.45	2,3
film to steel	0.14	6
Coefficient of Thermal Conductivity (film) (W/m/s/K) (See also Thermal Conductivity)		
100°C	37.5×10^{-3}	2,3
Coefficient of Thermal Expansion (film) (K^{-1})		
20°C–50°C	1.7×10^{-5}	2,3
Melt	6.55×10^{-4}	5
Coefficient of Volume Expansion (K^{-1})		7
Crystalline, below T_g	1.7×10^{-4}	
Crystalline, above T_g	3.94×10^{-4}	
Compressibility (melt) (MPa) ($\times 10^6$)	6.99	5
Conductivity for Direct Current See Fig. 1 overleaf		
Crystallographic Data See Unit cell		
Density (Mg/m^3) ≡ (g/cm^3)		
0% Crystalline	1.333	81
100% Crystalline	1.455	82
Amorphous, non-oriented	1.335	9
Partly cryst., non-oriented	1.385	9
Partly cryst., oriented	1.390	9
Highly cryst., non-oriented	1.420	10
Calculated, crystal	1.515	11
	(1.501)	12
Dielectric Strength (film) (V/cm)		2,3
23°C, 60 Hz	2.95×10^6	
150°C, 60 Hz	2.75×10^6	
Dielectric Constant (film)		2,3
23°C, 60 Hz	3.30	
23°C, 1 kHz	3.25	
23°C, 1 MHz	3.0	
23°C, 1 GHz	2.8	
150°C, 60 Hz	3.7	
Dissipation Factor (film)		2,3
23°C, 60 Hz	0.0025	
23°C, 1 kHz	0.0050	
23°C, 1 MHz	0.016	
23°C, 1 GHz	0.003	
150°C, 60 Hz	0.00040	
Elastic Constants (filaments) (Pa^{-1})		13
Oriented		
S_{11} transverse	16×10^{-10}	
S_{33} longitudinal	0.71×10^{-10}	
S_{44} torsional	14×10^{-10}	
S_{12}	-5.8×10^{-10}	
S_{13}	-0.31×10^{-10}	
Unoriented		
S_{11} or S_{33} extensional	4.4×10^{-10}	
S_{44} torsional	11×10^{-10}	
Enthalpy of Fusion (kJ/mol)	2.69	10
Entropy of Fusion (J/mol/K)	48.6	10
Folding Endurance (film) (cycles)		
23°C	300 000	2,3

*Value sensitive to semicrystalline morphology.

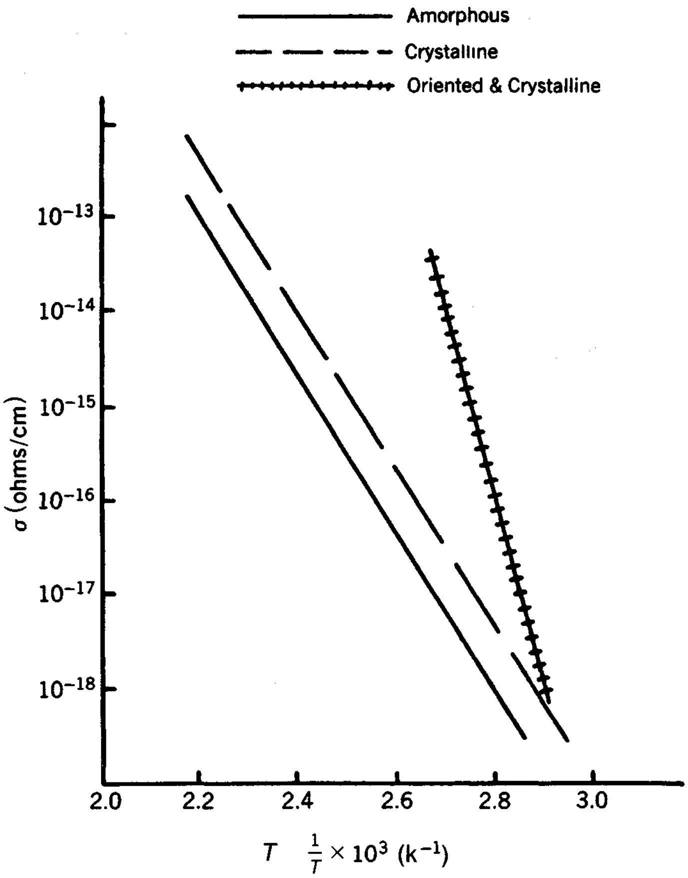

Figure 1. Direct current conductivity at various temperatures and degrees of orientation and crystallinity (8).

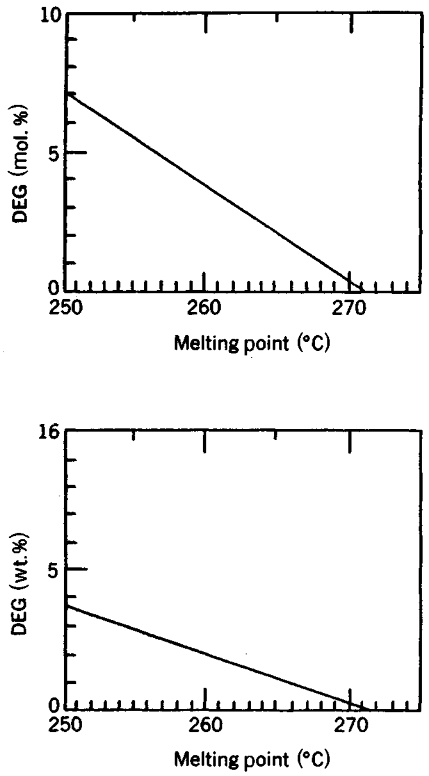

Figure 2. Effect of diethylene glycol (DEG) content on melting point. Melting point (°C) = 271–273 (2,29).

Property	Value	Refs.
Glass Transition Temperature* (°C)		
Amorphous	67	7,14
Crystalline	81	14
Crystalline and oriented	125	15
Heat capacity See Specific heat		
Heat of Combustion (kJ/kg)	-2.16×10^4	16
Heat of Sorption (film) (kJ/kg/mol)		
Carbon dioxide	-3.1×10^4	17
Methane	-2.3×10^4	
Solubility of Carbon Dioxide		
25–115°C, 0–20 atm		83
Hygroscopic Coefficient of Expansion (film) (cm/cm%/RH)		
20–92% RH,	1.1×10^{-5}	2,3
Impact Strength (film) (J/m)		
23°C	2.4×10^2	2,3
Infrared Spectra See Refs. 18–25		
Insulation Resistance (film) (Mohm mfds)		
100°C	5000	26,27,28
130°C	400	
150°C	100	

*Value sensitive to semicrystalline morphology.

Physical Constants of Poly(oxytetramethylene-oxyterephthaloyl) and Copolymers with Tetramethylene Oxide Thermoplastic Elastomers*

K. B. Wagener
Department of Chemistry and Center for Macromolecular Science & Engineering, University of Florida, Gainesville, FL, USA

The literature gives different chemical abbreviations for this segmented polyester/polyether copolymer, such as PBT/PTMO, PBT/PTHF (where PTHF abbreviates polytetrahydrofuran), and PBT/POTM (where POTM abbreviates polyoxy-tetramethylene). Occasionally, components of the abbreviation are reversed (as in PTHF/PBT). All these abbreviations represent the same copolymer, which is available with different weight percentages of polyether being present.

	Weight percentage polyether in copolymer[a]					
Property	0%[b]	10%	25%	35%	50%	60%
Hardness, shore D	80	74	63	55	45	38
Density (mg/m^3)	1.30	1.27	1.23	1.20	1.16	1.12
Coefficient of expansion (vol/K)						
@ − 20°C	210×10^{-6}	240×10^{-6}	360×10^{-6}	300×10^{-6}		
20°C	210×10^{-6}	330×10^{-6}	420×10^{-6}	450×10^{-6}	480×10^{-6}	660×10^{-6}
80°C		510×10^{-6}	540×10^{-6}	600×10^{-6}		
THERMAL PROPERTIES						
Glass transition temp. (°C)	55 /48[c]	44 /24[c]	2 /− 28[c]	− 23 /− 46[c]	− 50	− 60
Heat capacity, C_p (kJ kg/K) @ 100°C	1.35	1.61	1.72	1.78	1.95	2.01
Melting temperature (°C)	223	221	210	202	183	192
Heat of fusion (kJ/kg)	54	60	41	38	29	25
ELECTRICAL PROPERTIES						
Dielectric constant (1 kHz)	3.0	3.35	4.1	4.3	4.5	4.5
Dissipation factor (1 kHz)	0.002	0.037	0.017	0.012	0.006	0.005
Volume resistivity (ohm m)	5.10×10^{14}	8.8×10^{13}	1.2×10^{11}	2.5×10^{10}		
MECHANICAL PROPERTIES						
Ultimate elongation (%) (ASTM D 412)	200	360	540	570	700	650
Tensile strength (MPa) (DIN 53504)	52	45	38	32	21	17
Initial slope of stress–strain curve, Young's modulus (MPa)	2600	830	300	170	90	53
Storage modulus G′ (log MPa)	2.74	2.70	2.17	1.94	1.60	1.25
Loss modulus G″ (log MPa)	0.78	1.58	0.96	0.48	0.08	− 0.27
Loss tangent G″/G′	0.011	0.076	0.062	0.035	0.03	0.03
Resilience (rebound) (%)			40	53	60	65

[a] $\bar{M}_n = 1000$ for the polyether except for the 60 wt.% copolymer, in which $\bar{M}_n = 2000$.
[b] 0% refers to the properties for pure poly(oxytetramethylene-oxyterephthaloyl) (poly(butylene terephthalate)).
[c] Two different measurement values are given, top tan ∂/top G″, 1 Hz.
[d] Top of highest peak.

* All data are unpublished results from the Akzo Fibers and Polymers Research Laboratories, Arnhem, The Netherlands.

Physical Constants of Various Polyamides: Poly[imino(1-oxohexamethylene)], (Polyamide 6) Poly(iminoadipoyl-iminohexamethylene), (Polyamide 66) Poly(iminohexamethylene-iminosebacoyl), (Polyamide 610) Poly[imino(1-oxododecamethylene)], (Polyamide 12)*

A. INTRODUCTION

For the present edition of *Polymer Handbook* the former chapter, "Properties of Cellulosic Materials" has been considerably shortened and restructured. Besides leaving out the infrared spectrum and some properties not considered genuinely physical, the main alteration is the omitting of the vast field of cellulose derivatives altogether. This is to be justified in view of the space given to the other polymers dealt with in the section, "Physical Constants of Some Important Polymers". Each of the cellulose derivatives (or at least each class), we think, would have required an entry of its own. Accordingly, we restricted ourselves to materials, the main component of which is native or regenerated cellulose. Therefore, we explicitly refer to the previous edition (1) for its wealth of data on cellulose derivatives, liquid crystals therefrom, nonglucose hydrocarbons and noncellulosic substances in cellulosic materials, and first order rate constants and energies of activation of homogeneous hydrolysis. Moreover, much useful and recent information can be found in the Proceedings of the Cellucon Conferences (2), the pertinent ACS volumes (3) and a number of monographs (4–9), whereas cellulose research before 1955 is well documented in Refs. (10,11).

* Based on the table in the third edition, by A. Gröbe, Fraunhofer-Institut für Grenzflächen-und Bioverfahrenstechnik, Stuttgart, Germany.

B. SOLID STATE PROPERTIES

TABLE 1. UNIT CELL DIMENSIONS[a]

Modification	Space group	*a* (Å)	*b* (Å)	*c* (Å)	*α* (°)	*β* (°)	*γ* (°)	Remarks	Refs.
I_α	P1	6.74	5.93	10.36	117	113	81	Natural occurrence (algae, bacteria)	12,13[b,c]
I_β	$P2_1$	7.85	8.14	10.34	90	90	96.6	Natural occurrence (higher plants)	14[c],15[b],16[b]
II	$P2_1$	8.01	9.04	10.36	90	90	117.1	Obtained by alkali treatment	17[c],18[b]
III		10.25	7.78	10.34	90	90	122.4	Obtained by liquid ammonia treatment	19
IV		8.01	8.12	10.34	90	90	90	Obtained by heat treatment of cellulose III	20

[a] Due to the very limited number of available X-ray reflections, atomic coordinates are difficult to determine. The question of chain orientation (parallel *vs.* anti-parallel packing) cannot be considered ultimately settled, although a parallel arrangement is widely accepted for Cellulose I, whereas Cellulose II is thought to crystallize in an anti-parallel packing mode. In each of the five cells given in the table, the *c* axis is parallel to the chain axes. The I_α cell contains a single chain with two glucose units, while all the other cells consist of two chains with two glucose units each.
[b] References deal with the same modification.
[c] Atomic coordinates given.

TABLE 2. DENSITY

Type of cellulose	Density (g/cm^3)	Refs.
Cellulose I	1.582–1.630[a]	21,22,23,24,25,26,27
Cellulose I_α	1.58[a]	12
Cellulose I_β	1.62–1.64[a]	14,16
Cellulose II	1.583–1.62[a]	22,24,28,26
Cellulose IV	1.61[a]	22
Cotton	1.545–1.585	29,30,31,32,33,34
Ramie	*ca.* 1.55	26,35
Flax	1.541	36
Hemp	1.541	36
Jute	1.532	36
Wood pulps	1.535–1.547	26,31,37,25,38,39,33
Cuprammonium fibers	1.519–1.531	31,32,34
Polynosics	1.489–1.528	40,41
Viscose fibers (and films) (rayon and staple)	1.508–1.548	31,32,38,42,43,44
High tenacity viscose fibers	1.498–1.524	42,45

[a] Calculated from X-ray or electron diffraction data.

TABLE 3. AVERAGE ORDERED FRACTION OF COTTON AND LINTERS MEASURED BY VARIOUS TECHNIQUES[a,b]

Technique	Average crystallinity value for cotton and linters (%)	Number of publications involved in the average crystallinity value	Approximate average crystallinity value	
			Wood pulp	Regenerated cellulose
PHYSICAL				
X-ray diffraction	73	25	60	35
Density	64	18	50	35
ABSORPTION AND "SWELLING" CHEMICAL				
Deuteration	58	5	45	25
Moisture regain	58		50	25
Hallwood–Horrobin	67	3	55	35
Nonfreezing water	*ca.* 85	1		50
Acid hydrolysis	90	26	85	70
Alcoholysis	*ca.* 90	4		
Periodate oxidation	92	4	92	80
Nitrogen tetroxide oxidation	*ca.* 70	1		50
Formylation	79	7		35
Iodine sorption	87	9	85	60
"NONSWELLING" CHEMICAL				
Chromic acid oxidation	99.7	1		
Thallation	99.6	2		

[a] Ref. 46.
[b] Most of these values are general averages of several published values: the number of publications involved in each average is given in the third column. The term "crystallinity value" does not imply that any particular method measures crystallinity or order in any strictly defined sense, or that the various methods measure precisely the same type or level of order/disorder; with the chemical methods for instance, the value given is merely the fraction of the material that is not readily accessible to, and thus not able to, react with the particular reagent.

TABLE 4. AVERAGE ORDERED FRACTION MEASURED BY VARIOUS TECHNIQUES[a]

Technique	Cotton	Mercerized cotton	Wood pulp	Regenerized cellulose
X-ray diffraction	0.73	0.51	0.60	0.35
Density	0.64	0.36	0.50	0.35
Deuteration or moisture regain	0.58	0.41	0.45	0.25
Acid hydrolysis	0.90	0.80	0.85	0.70
Periodate oxidation	0.92	0.90	0.92	0.80
Iodine sorption	0.87	0.68	0.85	0.60
Formylation	0.79	0.65	0.75	0.35

[a] According to Hermans (49a) relative and absolute X-ray methods can be distinguished. DC and x_c values are absolute ones as well as some of the Cr values. The Ruland–Vonk-method provides additionally a lattice disorder factor k representing the amount of lattice distortions. The so-called crystallinity index or ratio values derived from relative methods as peak height ratios are omitted here. For these, the reader is referred to the third edition (1).
[b] According to Hermans and Weidinger (47,48).
[c] According to the method of Ruland (86) and Vonk (87).
[d] According to other methods.

			>0.9	67
Tencel			0.94	123
Lyocell-type fibers wet			0.33–0.35	124

[a] For native fibers the spiral angle Φ between cellulose microfibrils (crystallites) and fiber axis is filed. The degree of uniaxial orientation of crystallites is given for regenerated fibers and some of the native by the Hermans orientation factor, f_x, according to Ref. (10). As existing data for regenerated fibers largely depend on spinning conditions, ranges of f_x are given.

[a] The constant pressure specific heat capacity $C_p(T)$ as a function of temperature T is expressed in linear approximation as $C_p(T) = C_p(T_0) + a\,(T - T_0)$, $T_0 < T_m$, a being the slope and T_m marking the interval of validity.

TABLE 12. RESISTIVITY

Material	ρ^a (Ω cm)	R_s^b (Ω/gcm²)	Remarks	Refs.
Pure cellulose	10^{18}			229,230
Cotton	2×10^7		52% RH[c], 30°C, moisture dependence investigated	231
		7×10^6	65% RH, 20°C	231
	2.4×10^9		35% RH, 0.18 GPa static pressure	232
Raw cotton	8×10^5		75% RH, 25°C	233,234[d]
	5×10^5			233,234[d]

TABLE 12. *cont'd*

Material	ρ^a(Ω cm)	R_s^b(Ω gcm^{-2})	Remarks	Refs.
Cotton, washed	12×10^6 – 37×10^6		$M^e = 10\%$, 20°C, moisture dependence investigated	234
Cotton, purified	9.3×10^5		$M = 10\%$, 20°C, moisture dependence investigated	234
Ramie	6×10^4 – 1.8×10^6		$M = 10\%$, 20°C, moisture dependence investigated	234
Ramie, purified	5.7×10^6		$M = 10\%$, 20°C, moisture dependence investigated	234
Hemp	1×10^7		$M = 10\%$, 20°C, moisture dependence investigated	234
Jute, purified	2.5×10^8		$M = 10\%$, 20°C, moisture dependence investigated	234
Flax, purified	6.6×10^6		$M = 10\%$, 20°C, moisture dependence investigated	234
Viscose rayon	1×10^6 – 3×10^6		≈80% RH, 30°C, moisture dependence investigated	234
		10^8 – 10^9	$M = 10\%$, 20°C, moisture dependence investigated	234
	6.75×10^{10}		35% RH, 0.18 GPa static pressure	232
Cuprammonium rayon		2.6×10^8	$M = 10\%$, 20°C, moisture dependence investigated	234
Fortisan		3.5×10^7	$M = 10\%$, 20°C, moisture dependence investigated	234
Mercerized cotton		6.6×10^6	$M = 10\%$, 20°C, moisture dependence investigated	234
Regenerated cellulose	10^{17}			229
Cellophane cuprophane	10^{10} – 3×10^{12}		65% RH, 20°C	235
Insulating paper	$\approx 2 \times 10^{14}$		Air dry	236
	5×10^{17}		$M < 1\%$	237
	10^{12}		$M = 12\%$	237
	10^{14}		20°C, air dry	238
	10^{11}		100°C, air dry	238
Insulating kraft paper	4×10^{17}		20°C	239
	1.2×10^{17}		100°C	239

[a] Specific resistance (resistance of unit cross section per unit length).
[b] Mass specific resistance (product of ρ and density).
[c] Relative humidity.
[d] These references give additional data.
[e] Moisture content (wt.%).

TABLE 13. DIELECTRIC CONSTANT AND LOSS FACTOR AT 1 kHz[a]

Material	ε^b	tan δ^c	Range of lg^d (ν)^e	Remarks	Refs.
Pure cellulose (from spruce)	7.2	0.02	2–8	Bone dry, 20°C	240
Cotton	3.2	<0.02		Bone dry, 21°C	241
	6.1			25°C	242
	2.76		3–4	Unbeaten, density 1.0 g/cm^3	243
	2.85–3.05		3–4	Beaten, density 1.0 g/cm^3	243
	4.6	0.03	2–7	Dry, 0°C, temperatures up to 60°C investigated	244
Jute	105	1.4	2–5	Along fiber	245

NaOH type	16–17	4–6	15–21	16–23	971–1290	25–63	276

[a] To convert to MPa multiply value by ten times the density value when expressed in g/cm^3.
[b] Data taken from references 76,267–269.

C. SOLUTION PROPERTIES

TABLE 17. TYPICAL NON-AQUEOUS CELLULOSE SOLVENTS[a,b,c]

Number of components	Substance group	Examples
Unicomponent	*N*-Alkylpyridinium halogenides	Ethylpyridinium chloride
	Oxides of tertiary amines	*N*-Methylpiperidine-*N*-oxide
		N-Methylmorpholine-*N*-oxide
		N,N-Dimethylcyclohexylamine-*N*-oxide
Bicomponent	Dimethyl sulfoxide (DMSO) containing solvents	DMSO/methyl amine
		$DMSO/CaCl_2$
	Liquid ammonia/sodium or ammonium salts	NH_3/NaI (NH_4I)
		$NH_3/NaSCN$ (NH_4SCN)
		$NH_3/NaNO_3$
		$NH_3/N(C_2H_5)_4Br$
	Dipolar aprotic solvents/LiCl	*N,N*-Dimethyl acetamide (DMA)/LiCl
		N-Methylpyrrolidone/LiCl
		N-Methylcaprolactam/LiCl
		N-Hexamethyl phosphoric acid triamide/LiCl
		Dimethyl urea/LiCl
	Pyridine or quinoline containing systems	Pyridine/resorcinol
		Quinoline/$Ca(SCN)_2$
	Liquid SO_3/secondary or tertiary amines	SO_3/ triethyl amine
Tricomponent	NH_3 or amine/salt/polar solvent	NH_3/NaCl/morpholine
		NH_3/NaCl/DMSO
		Ethylene diamine/NaI/*N,N*-dimethyl formamide
	NH_3 or amine/SO_2 or $SOCl_2$ polar solvent	Diethylamine/SO_2/DMSO

[a] A very extensive list including sketches of phase diagrams, is given in Ref. (1).
[b] In most cases a preactivation of the cellulose is required.
[c] Ref. 277.

TABLE 18. OTHER SOLVENTS[a]

Substance group	Examples	Refs.
Mineral acids[b]	HCl, HBr	279
	H_2SO_4	280,281
	HNO_3	282,283,284
	H_3PO_4	280,285,281
	Trifluoroacetic acid	286,287,288,289,290
Inorganic salts in aqueous solution	LiCl	291,292,293
	$ZnCl_2$	281,294,295
	$Ca(SCN)_2$	296,297,298,299,300
Inorganic salts in concentrated solutions or melts, single and/or multicomponent systems	$Ca(SCN)_2$	298,301
	LiCl, LiJ, LiSCN, $CaBr_2$, $Ca(SCN)_2$	302
	$Ca(SCN)_2/CH_2O$	303
	$LiSCN \cdot 2.5H_2O$	304,305
	$KSCN + NaSCN + Ca(SCN)_2 \cdot 3H_2O$	304,305
	KSCN + NaSCN + DMSO	304,305
	$Ca(SCN)_2 \cdot 3H_2O + CH_2O$	304
	LiSCN, NaSCN, LiJ, NaJ, KJ	306,46
Strong bases in aqueous solution	LiOH	307
	NaOH	307,81
	NaOH + ZnO	307,308,309
Strong bases in aqueous solution	NaOH + BeO	307,308
Tetraalkyl bases (molecular weight >150)	Tetraethylammoniumhydroxide and some higher homologs	310,311,312
	Trimethylbenzylammoniumhydroxide ("Triton B")	313,311
	Dimethyldibenzylammoniumhydroxide ("Triton F")	313,311
	Tetraalkylphosphonium hydroxides	314
	Tetraalkylarsonium hydroxides	144
	Trialkylsulfonium hydroxides	315
	Trialkylselonium hydroxides	292
Metal complex solutions	$[Cu(NH_3)_4](OH)_2$ ("Cuoxam", "Cuam")	316,317
	Modified cuoxam	170
	$[Cu(en)_2](OH)_2$ ("Cuprieethylenediamine", "Cuene", "CED")	318,319
	Cu : biuret : alkali	320
	$[Co(en)_3(OH)_2$ ("Cooxene")	321,322
	$[Ni(NH_3)_6](OH)_2$ ("Nioxam")	323,324
	$[Ni(en)_3](OH)_2$ ("Nioxene")	323,325
	$[Zn(en)_3]$ $(OH)_2$ ("Zincoxene")	323,325
	$[Cd(en)_3](OH)_2$ ("Cadoxene")	323,326,327
	Complex solution of the Na-salt of Fe-tartaric acid in diluted NaOH solution ("FeTNa")	323,328

[a] Excerpt from the table in Ref. (1); cf. also (278) as a modern reference.
[b] Dissolution usually accompanied by strong degradation of the cellulose chains.

10% NaOH solution	0.43	1.0			20	U	OS	363

[a] The constants K_m and a given in the table are defined by the equation $[\eta] = K_m M^a$, $[\eta]$ and M being intrinsic viscosity and molecular weight, respectively. G is the shear rate.
[b] Osmotic measurements.
[c] Fractionated.
[d] Viscosimetric comparison.
[e] Unfractionated.
[f] Measurement by sedimentation–diffusion.
[g] Cellulose nitrate used for calibration.
[h] Measurement by light scattering.
[i] Measurement by sedimentation.
[j] From kinetic data.
[k] See also Table 17, Typical Non-Aqueous Cellulose Solvents.

TABLE 20. SECOND VIRIAL COEFFICIENT

The second virial coefficient listed in the table below is defined by the equation

$$\pi/c = \mathrm{RT}[1/\mathrm{M} + A_2c + A_3c^2 + \cdots]$$

where π is the osmotic pressure, C the concentrations R the gas constant, T the temperature, M the molar mass, and A_3 the third virial coefficient.

Solvent[c]	T (°C)	DP[a] range	Range of A_2 ($\times 10^3$) (cm^3mol/g^2)	Remarks	Refs.
Cuoxam	20	195–12500	0.8–3.0	No trend, $V^b = 12$	367
Cadoxene	25	175–5820	1.1–1.8	No trend, $V = 9$	352
FeTNa	25	230–3950	3.0–4.4	No trend, $V = 10$	360
LiCl/DMAc	30	770–4320	3.5–5.3	Monotonous decrease (one outlier), $V = 9$	361

[a] Degree of polymerization.
[b] Number of single values given.
[c] See also Table 17, Typical Non-Aqueous Cellulose Solvents.

TABLE 21. SEDIMENTATION AND DIFFUSION COEFFICIENTS

The sedimentation and diffusion coefficients for non-vanishing concentrations s and D, respectively, are calculated from $s^{-1} = s_0^{-1}$ $(1 + k_s c)$ and $D = D_0(1 + k_D c)$, respectively, with s_0, D_0, d_s and k_D listed in the table, where c is the cellulose concentration.

Solvent[a]	T (°C)	M^b ($\times 10^{-3}$) (g/mol)	s_0 ($\times 10^{13}$) (s)	k_s (cm^3/g)	D_0 ($\times 10^7$) (cm^2/s)	k_d (cm^3/g)	Refs.

TABLE 23. GEOMETRICAL CHAIN CHARACTERISTICS

Listed properties:

Characteristic ratio	$C_\infty = \langle R^2 \rangle_0/(nl^2)$
Unperturbed chain dimension	$A = \{\langle R^2 \rangle_0/M\}^{1/2}$
Conformation parameter	$\sigma = \langle R^2 \rangle_0/\langle R^2 \rangle_{0,f}$
Persistence length	$q = \lim\{\langle Rl_1 \rangle\}/l$ with $nl \to \infty$
Linear expansion coefficient	$\alpha_s = \{\langle s^2 \rangle/\langle s^2 \rangle_0\}^{1/2}$

where

- $\langle R^2 \rangle_0$ – Averaged squared chain end-to-end vector in unperturbed state
- n – Degree of polymerization
- l – Monomer unit length (5.18 Å)
- M – Molar mass
- $\langle R^2 \rangle_{0,f}$ – Same as $\langle R^2 \rangle_0$, but for freely rotating chain
- $\langle Rl_1 \rangle$ – Averaged projection of chain end-to-end vector onto first bond-vector
- $\langle s^2 \rangle$ – Averaged squared radius of gyration
- $\langle s^2 \rangle_0$ – Same as $\langle s^2 \rangle$ for the unperturbed state.

Property	Solvent[a]	T (°C)	Value	Remarks	Refs.

TABLE 24. POLYMER–SOLVENT INTERACTION PARAMETERS

This parameter χ (Flory–Huggins parameter) figures in the equation for the reduced partial molar Gibbs energy of mixing of the solvent $\Delta G_1/RT$ (R – gas constant, T – temperature) in the following way:

$$\Delta G_1/RT = \ln(1 - \varphi_2) + \varphi_2 + \chi\varphi_2^2$$

φ_2 being the volume fraction of the polymer (cf. the corresponding chapter in this Handbook).

Solvent	Concentration (wt.% cellulose)	χ	Remarks	Refs.
Water	Saturated with water	0.124	25 °C, cotton fiber	373
		0.435–0.44	25°C, viscose rayon	373
		0.528	25°C, cellophane	373
$NMMO \cdot 1H_2O$[a]	5–15	−3	Melting point depression	374
		0.5		
NMMO		0.35–0.40		375
NMMO with 13–15 wt.% water	3–15	<−20	DP ~450, concept not applicable	376

[a] NMMO-*N*-methylmorpholine-*N*-oxide.

A. INTRODUCTION

This section of *Polymer Handbook* focuses on critical polymers in the commercial world. The polymers were chosen because they already have a large economic impact or are likely to have an economic impact during the lifetime of this Handbook. Hundreds of polymers are the subjects of study and application in the world. Many of these have commercial status. However, including all of them would compromise the utility of this chapter. Properties for all the polymers of this section plus many others are included with more details in various chapters of this Handbook.

Because of their cost and properties, polymers in this section often get first consideration for applications, or are the benchmarks against which alternative materials are compared. The data in the tables of this section can be used for rapid comparison against performance requirements.

Brief narrative descriptions of the polymers are given in the next section. More complete descriptions can be found in other places; the Handbook of Plastic Materials and Technology (I. I. Rubin (Ed.), Wiley Interscience, 1990) is an excellent resource.

A common set of properties are given in Section C. In many cases, the data are not available or are not relevant. In some cases, we have chosen to highlight a specific example of a family of polymers. However, in some cases, selecting a single member of a family did not represent the range of applications and properties available, so we included the ranges or subclassifications. Often the sources of data on polymer properties disagree. We have assumed that the disagreements were honest results of subtle differences in the polymer or the test. In some cases we report averages, in some cases we report the "best" value, and in other cases we report ranges. The reader is advised to refer to the specific product literature and to consult the technical service representatives of the suppliers. Standard or typical abbreviations for each polymer are also included.

B. NARRATIVE DESCRIPTIONS

1. Multipurpose Polymers

Poly(ethylene terephthalate) (PET) This polymer is usually made by a two-step condensation polymerization of the dimethyl ester of terephthalic acid and ethylene glycol. Articles made with this polymer can be either semi-crystalline or amorphous. Applications include fibers for carpeting and clothing, bottles (especially for soft drinks), and films for food packaging and magnetic tapes.

Poly(ethylene terephthalate, 1,4-cyclohexane dimethanol) (PETG) This polymer substitutes enough 1,4-cyclohexane dimethanol for ethylene glycol in the backbone (to prohibit crystallization). Applications include food packaging and injection molded parts.

Poly(vinyl chloride) (PVC) Applications for this polymer fall into two broad categories depending upon formulation. The name for this polymer is often freely abbreviated as "vinyl".

Flexible poly(vinyl chloride) This type typically contains 30–40 wt.% additives, especially plasticizers, to lower the glass-transition temperature. Applications include hoses, films, flooring, and automotive interiors.

Rigid poly(vinyl chloride) This glassy polymer is used for molding and profile extrusions with less additives. Typical applications include pipe, house siding, window frames, and bottles.

Ethylene–methacrylic acid copolymers, partially neutralized with sodium or zinc (Ionomer) The most important applications are for food packaging as films or sheets. They adhere to nylon in coextrusion, and they heat seal well.

Ethylene–acrylic acid copolymers (EAA) These adhesive copolymers typically have between 3 and 20 wt.% acrylic acid. They are often used in extrusion coating to provide a heat seal layer for packaging, especially when good flavor/aroma retention is needed.

Ethylene–vinyl acetate copolymers (EVA) The range of compositions can be from 2–50 wt.% vinyl acetate. Tough, clear films are made with copolymers having low levels of vinyl acetate (2–7 wt.%). Hot melt adhesives are an application for higher levels of vinyl acetate (18–40 wt.%).

Polytetrafluoroethylene (PTFE) This homopolymer of tetrafluoroethene has a wide range of valuable properties. Applications often rely on the very low surface energy (useful for non-stick coatings), the chemical resistance to many liquids (useful for gaskets and liners), and the wide range of service temperatures.

Ethylene–styrene interpolymers (ESI) These copolymers exhibit a very wide range of properties depending on composition. At low levels of styrene, the copolymers are crystalline, flexible, thermoplastics. At intermediate levels of styrene, the copolymers are amorphous and highly elastomeric. At high levels of styrene, the copolymers have a mixture of glassy and rubbery properties with a glass-transition temperature ranging to above room temperature. Applications vary as widely as the properties, including new areas for thermoplastics.

Poly(lactic acid) (PLA) This compostible polymer is synthesized from renewable resources. The properties vary according to the composition (D- and L- conformations). Applications include food packaging as film or molded cups.

2. Polyolefins and Barrier Polymers

Polyethylene family The total usage of all members of this family is the greatest of all thermoplastics. Most members of the family are easy to fabricate and have low cost. The properties vary widely across the family. Food packaging is a frequent application.

High density polyethylene (HDPE): This set of highly crystalline polymers is used in molding and film applications, with milk jugs being a prime example. These polymers are less flexible than other polyethylenes.

Low density polyethylene (LDPE): This set of branched polymers is less crystalline than HDPE. Members are flexible and clear, with moderate toughness.

Linear low density polyethylene (LLDPE): These are copolymers of ethylene with modest amounts of butene, hexene, or octene linear α-olefins. Grades are available for films and for molding. Films typically show good toughness. Some grades are suitable for fibers.

Very low density polyethylene or ultra-low density polyethylene (VLDPE or ULDPE): These are also copolymers of ethylene and linear α-olefins; however, they have densities less than 0.915 g/cm^3. They have improved toughness and sealability compared to LLDPE.

Polyolefin plastomer (POP): New catalyst technologies allow synthesis of these materials which include these with lower densities. Copolymers over a wide range of composition yield a wide range of properties for films, fibers, and molding applications.

Polypropylene (PP) Most applications use the isotactic form. Oriented (OPP) and unoriented films are used often for food packaging, sometimes in combination with vinylidene chloride copolymers. Polypropylene fibers are used for webbing in outdoor furniture, carpets, and both woven and non-woven fabrics. Polypropylene is also an important engineering thermoplastic.

Vinylidene chloride copolymers (PVDC) This set of polymers includes resins for extrusion and molding, resins for solution coating, and latexes for coating. A variety of comonomers are used to achieve different properties. The barrier properties are important for food packaging. Typically, these polymers are used with other polymers such as polyethylene or polypropylene in multi-layer structures.

Ethylene–vinyl alcohol copolymers (EVOH) These polymers are actually hydrolyzed copolymers of ethylene and vinyl acetate. They are excellent barriers to mass transport, especially when dry. They find applications in both flexible and rigid packaging for food, typically as part of a multi-layer structure.

3. Styrenics and Engineering Thermoplastics

Polystyrene family These inexpensive polymers span the range of engineering thermoplastics. They are easy to fabricate by either extrusion or molding. Typically, small amounts of additives are used, including extrusion aids, mold releases, FR agents, UV stabilizers, and plasticizers.

General purpose polystyrene (GPPS): This homopolymer is transparent and glossy. It quickly sets after molding to give stiff parts. Polystyrene can be made into foam articles such as insulating board or cups, using extrusion techniques or by expanding beads. Other applications include food packaging and molded parts in appliances.

High impact polystyrene (HIPS): This rubber-modified composite typically contains 1–10 wt.% rubber, generally polybutadiene, to give added toughness. It is also used in many applications including food packaging and molded parts.

Styrene–Acrylonitrile copolymers (SAN): A typical copolymer has 70 wt.% styrene and 30 wt.% acrylonitrile. These clear polymers have excellent dimensional stability and long-term toughness. Furthermore they are resistant to a wide range of solvents.

Rubber-modified styrene–acrylonitrile copolymers (ABS): This material has a continuous SAN phase with about 15 wt.% rubber modification, generally polybutadiene. In most applications, impact resistance is the reason for the selection of ABS. Applications include housings and covers for appliances and tools, plus a variety of automotive moldings.

Syndiotactic polystyrene (SPS): This semi-crystalline polymer can be used at higher temperatures. Applica-

tions include molded parts that must maintain close tolerances.

Polycarbonate (PC) This polymer is usually made in large scale by the condensation of phosgene and bisphenol A. It has great impact strength and excellent optical properties; hence, it is used for lenses, compact discs, glazing, instrument panels, and high-volume food services wares. It can be modified with reinforcing fibers, FR agents, and stabilizers. Development of new applications is intense.

Nylon family These are polyamides resulting from the condensation reaction of an amine function and an acid function. As a family, they are tough and hard. They are resistant to many liquids and have low coefficients of thermal expansion. They can be reinforced with glass fibers, carbon, and minerals. Applications include molded parts for electrical power transmission, molded parts for a wide range of automotive functions, pulleys, bearings and items which need good abrasion resistance and toughness.

Nylon 6: This homopolymer of caprolactam is in the middle of the range of nylons for toughness, hardness, and heat distortion.

Nylon 6,6: This copolymer of hexamethylene diamine and adipic acid has the greatest hardness and highest resistance to heat deformation and lowest toughness of the nylon family.

Poly(methyl methacrylate) (PMMA) This important member of the acrylate family is often freely abbreviated "acrylate". It has moderate toughness and excellent optical properties. It is hard. Hence, applications include glazing, fibers for transporting light, instrument panels, and packaging.

Polyoxymethylene (Acetal) Acetal resins are derived primarily from formaldehyde although copolymers are common. Endcapping is done to reduce the rate of degradation. These polymers are strong, tough, and stiff, and they have a low coefficient of friction against many materials. They are creep resistant and are extremely resistant to fatigue. Applications are often based upon dimensional stability and solvent resistance.

4. Elastomers

Poly(organosiloxanes) (silicone polymers) Most silicone polymers are either homopolymers or copolymers of dimethylsiloxane. They have high flexibility over a wide range of temperatures. They "repel" water strongly. Membranes are an important application for elastomeric grades. Other applications include stopcock grease, car polishes, and anti-stick formulations.

Chlorinated polyethylene (CPE) After a starting polyethylene has been chlorinated, the resulting material is typically 25–50 wt.% chlorine. The properties range from thermoplastic to elastomeric. Applications for CPE include automotive hoses, tubing, and wire jacketing plus extensive membranes for roofing. It can be an impact modifier for PVC.

Polyolefin elastomers (POE) These copolymers of ethylene and an α-olefin are made with single-site catalysts. They have very low densities. Materials can be designed for a wide range of applications.

Polyurethane elastomers (some TUP, thermoplastic polyurethane) These terpolymers can be used uncured for most applications; however, selected grades can be cross-linked to enhance properties. As a family these elastomers are tough and wear resistant. They have excellent chemical resistance and flexibility. They can have excellent clearity. Applications include cable jackets, Automotive fascia, connectors, fittings, and many, many more.

Ethylene-Propylene-Diene Terpolymers (EPDM) These terpolymers typically contain a few percent of a diene such as hexadiene. This material is easy to fabricate and then is usually heat-treated at 125°C to 175°C to induce crosslinking. The physical properties are much different after crosslinking. Commonly, they are heavily formulated for applications which include wire jacketing systems, automotive hoses, and roof sheeting.

C. PROPERTIES OF COMMERCIAL POLYMERS

A. INTRODUCTION

These tables contain data for approximately 2700 polymers. In general, the format and organization of the tables follows that used in the 2nd edition of the "Polymer Handbook" (Section B: Crystallographic Data; Section C: Melting Points; Section D: Formula Index and Section E: References). The Formula Index is included as an aid to the searcher: it permits one to determine the polymer name used in these tables from the structural line formula for the polymer of interest.

To avoid the duplication of data for polymers appearing in both the Crystallographic Data and Melting Point tables, the entry in the Melting Point table has been flagged with an asterisk (*).

1. Nomenclature

Contrary to the rest of the *Polymer Handbook*, the ACS-IUPAC nomenclature proposals (1,2) for naming regular single-strand organic polymers have not been adopted for these tables. Basically, the nomenclature used in this portion of the *Polymer Handbook* is that of the 1st and 2nd editions and of the 1967 recommendations of the IUPAC Nomenclature Committee (3). The majority of polymers were named as the bivalent radical(s) comprising the constitutional repeating unit (CRU), with priority in naming given to (a) incorporation of important structural features (amide, ester, oxide, etc.) and (b) emphasis on symmetry of the CRU (when present). As in the past, many common polymers (poly(styrene), poly(vinyl chloride), etc.) were named according to source names.

In the majority of cases, the polymer was named according to its structure, particularly when the CRU was composed of two or more subunits following each other in a regular fashion. An example is poly(ethylene terephthalate). With more complicated structures, the CRU was divided into its possible subunits, each of which was treated as a bivalent radical and so named. One of the subunits was treated as the parent compound, for example, the "terephthalic acid" of the above example. For poly(amides) and poly(esters), the acid was chosen as the parent compound; for poly(urethanes) it was the isocyanate.

Whenever the CRU (or a portion thereof) exhibited a center of symmetry, naming began with the central subunit using Chemical Abstracts/IUPAC names for the constituent bivalent radicals (see under examples). Conjunctive names were used as needed in constructing names. For symmetrical units, this process of naming could be continued indefinitely.

Unsymmetrical bivalent units were named with replacement nomenclature, or from end to end, depending upon the complexity of the bivalent radical and the ease of naming by the alternative choices. Replacement nomenclature was used, for example, to name poly(hexamethylene 6-oxa-heptadecanediamide). The polymer from the symmetrical oxyacid would be named poly(hexamethylene oxydicapryl-amide).

More complicated structures without symmetry were named end to end. This method was particularly appropriate for the poly(oxides) of the form $-(R-O-R'-O)_n$ (and for the analogous sulfides, sulfones, ureas, and anhydrides) and for the poly(ω-amino acids) and for the poly (ω-hydroxy acids). The constitutional hydrocarbon subunits were ordered alphabetically in naming the polymer as, for example, in poly(methyleneoxy pentamethylene oxide).

For silicon-containing polymers, bivalent radical names replaced the source-based silane/siloxane names. For example, the source-named polymer, poly[(tetramethylsil-phenylene) siloxane], appears in these tables as poly(*p*-phenylene tetramethyldisiloxanylene).

For the regular polymers of multipeptides, a cyclic permutation of the individual peptide residues in the constitutional base unit was performed to permit alphabetical ordering without loss of directional or sequential sense. Thus, poly(alanylglycyl-proline) is the name given to polymers prepared form (ala-gly-pro), (gly-pro-ala), and (pro-ala-gly), but not from (ala-pro-gly) or from either of its cyclic permutations.

2. Examples of Polymer Names

2.1. Polymer Names Based on Source

Olefin, Vinyl, and Acyclic Polymers

$[-CH_2-CH_2-]_n$	Poly(ethylene)
$\begin{array}{l}[-CH-CH_2-]_n\\ \;\;\vert\\ \;\;CH_2-CH_3\end{array}$	Poly(1-butene)
$\begin{array}{l}[-CH-CH_2-]_n\\ \;\;\vert\\ \;\;CN\end{array}$	Poly(acrylonitrile)
$\begin{array}{l}[-CH-CH_2-]_n\\ \;\;\vert\\ \;\;Cl\end{array}$	Poly(vinyl chloride)
$\begin{array}{l}[-CH-CH_2-]_n\\ \;\;\vert\\ \;\;COOCH_3\end{array}$	Poly(methyl acrylate)

Poly(amides)[1]

$[-NH-CH_2-COO-]_n$	Poly(glycine)
$[-NH-(CH_2)_2-COO-]_n$	Poly(3-aminopropionic acid) (poly(β-alanine))
$[-NH-(CH_2)_3-COO-]_n$	Poly(4-aminobuyric acid)
$[-NH-(CH_2)_4-COO-]_n$	Poly(5-aminovaleric acid)
$[-NH-(CH_2)_5-COO-]_n$	Poly(6-aminocaproic acid)
$[-NH-(CH_2)_6-COO-]_n$	Poly(7-aminoenanthic acid)
$[-NH-(CH_2)_7-COO-]_n$	Poly(8-aminocaprylic acid)
$[-NH-(CH_2)_8-COO-]_n$	Poly(9-aminopelargonic acid)
$[-NH-(CH_2)_9-COO-]_n$	Poly(10-aminocapric acid)
$[-NH-(CH_2)_{10}-COO-]_n$	Poly(11-aminoundecanoic acid)
$[-NH-(CH_2)_{11}-COO-]_n$	Poly(12-aminolauric acid)

Poly(oxides)

$[-CH_2-O-]_n$	Poly(oxymethylene)
$\begin{array}{l}[-CHO-]_n\\ \;\;\vert\\ \;\;CH_3\end{array}$	Poly(acetaldehyde)

[1] Poly(esters) are treated similarly.

[$-CH_2-CH_2-O-$]$_n$	Poly(ethylene oxide)
[$-CH-CH_2-O-$]$_n$ (with CH_3 on CH)	Poly(propylene oxide)
[$-CH_2-CH_2-CH_2-O-$]$_n$	Poly(trimethylene oxide)

2.2. Polymer Names Based on Structure

(a) Linking Radicals

$-CH_2-CH_2-$	Ethylene
$-CH_2-CH_2-CH_2-$	Trimethylene
$-CH_2-CH_2-O-CH_2-CH_2-$	Oxydiethylene
$-CH_2-CH_2-O-CH_2-CH_2-O-CH_2-CH_2-$	Ethylenedioxy-diethylene
	Sulfonyldiethylene
$-CH_2-CH_2-CH_2-P(CH_3)-CH_2-CH_2-CH_2-$	methylphosphinidene-ditrimethylene
	*p*-Phenylenediethylene
	4,4′-Biphenylenediethylene
	4,4′-Methylenediphenylene
	4,4′-Ethylidenediphenylene
	4,4′-Isopropylidenediphenylene
	4,4′-Butylidenediphenylene
	4,4′-(2,2-Butylidene)diphenylene
	4,4′-Oxydiphenylene
	4,4′-Sulfonyldiphenylene

(b) Parent Compounds

$-OOC-COO-(-NHOC-CONH-)$	Oxalate (oxamide)
$-OOC-CH_2-COO-$	Malonate (malonamide)
$-OOC-(CH_2)_2-COO-$	Succinate (succinamide)
$-OOC-(CH_3)_3-COO-$	Glutarate (glutaramide)

$-OOC-(CH_2)_4-COO-$	Adipate (adipamide)
$-OOC-(CH_2)_5-COO-$	Pimelate (pimelamide)
$-OOC-(CH_2)_6-COO-$	Suberate (suberamide)
$-OOC-(CH_2)_7-COO-$	Azelaate (azelaamide)
$-OOC-(CH_2)_8-COO-$	Sebacate (sebacamide)
$-OOC-(CH_2)_9-COO-$	Nonanedioate (nonanediamide)
$-OOC-CH_2-CH_2-O-CH_2-CH_2-COO-$	Oxydipropionate
	*p*-Phenylene diacetate
	*p*-Phenylenedipropionate
	4,4′-Dibenzoate
	4,4′-Methylenedibenzoate
	4,4′-Oxydibenzoate
	4,4′-Sulfonyldibenzoate
	4,4′-Oxydiphenylenediacetate
	4,4′-(Ethylenedioxy)dibenzoate
	*p*-(Phenylenedioxy)diacetate
	(*p*-Carboxyphenoxy)acetate
	1,4-Piperazinediacetate

(c) Polymer Names

Poly(esters)[2]

	Poly(ethylene terephthalate)
	Poly(ethylene 4,4′-dibenzoate)
	Poly(ethylene *p*-phenylenediacetate)
	Poly(ethylene 4,4′-isopropylidenedibenzoate)
	Poly(ethylene 4,4′-sulfonyldibenzoate)

Poly(urethanes)

$[-CH_2-CH_2-CH_2-O-\overset{O}{\overset{\|}{C}}-NH-CH_2-CH_2-NH-\overset{O}{\overset{\|}{C}}-O-]_n$	Poly(trimethylene ethylene-urethane)

[2] Poly(amides) are treated similarly.

Poly(oxides), Poly(sulfides), Poly(amines)

$[\text{-}(CH_2)_2\text{-}O\text{-}(CH_2)_3\text{-}]_n$	Poly(ethylene trimethylene oxide)
$[\text{-}(CH_2)_2\text{-}S\text{-}(CH_2)_3\text{-}]_n$	Poly(ethylene trimethylene sulfide)
$[\text{-}(CH_2)_2\text{-}NH\text{-}(CH_2)_3\text{-}]_n$	Poly(ethylene trimethylene amine)

B. CRYSTALLOGRAPHIC DATA FOR VARIOUS POLYMERS

The following table presents crystallographic data for about 750 polymers (and for their many polymorphs) grouped, according to the generic structure of the constitutional base unit, into poly(olefins), poly(vinyls) and poly(vinylidenes), poly(aromatics) and poly(imides), poly(dienes) and poly(diynes), poly(peptides), poly(amides), poly(esters), poly(urethanes) and poly(ureas), poly(ethers), poly(oxides), poly(sulfides) and poly(sulfones), poly(saccharides), and other polymers. Where a polymer might be included in more than one group the following group definitions were used:

1. *Poly(olefins):* those olefin polymers not containing aromatic rings; all substituted derivatives of these, excluding the vinyl and vinylidene polymers. For example, poly(ethylene), poly(tetrafluoroethylene), and poly(cyclopentene), but not poly(styrene) or poly(vinyl chloride).
2. *Poly(vinyls) and Poly(vinylidenes):* those vinyl and vinylidene polymers containing atoms other than carbon and hydrogen, excepting the poly(ethers). Thus, poly(vinyl chloride) but not poly(methylvinyl ether).
3. *Poly(aromatics) and Poly(imides):* those hydrocarbon polymers containing aromatic rings, including heterocyclic ones. Thus, poly(styrene), poly(*p*-xylylene), and poly(*p*-phenylene pyromellitimide).
4. *Poly(peptides):* those polymers whose basic structure, ignoring substituents, is poly(2-aminoacetic acid), that is, poly(glycine). This group contains mainly the synthetic poly(α-amino acids).
5. *Poly(amides):* all amide polymers except the poly(α-amino acids), which are separately grouped under poly(peptides).
6. The remaining categories contain polymers according to functional groups as, for example, the poly(esters). Poly(ethers) and poly(oxides) are differentiated according to whether the ether linkage is in the side-group or in the chain backbone, respectively. For example, poly(1-butoxy-2-chloroethylene) is a poly(ether) and poly(oxymethylene) is a poly(oxide).
7. Those polymers not otherwise categorized, such as the poly(phosphazenes) and the poly(siloxanes), are grouped in the "other" category.

Within each group, polymers are listed alphabetically according to the basic structure, ignoring substituents (excepting the polypeptides, all of which have the same base structure). Substituted polymers are listed alphabetically according to the substituent under the entry for the unsubstituted polymer. Thus, poly(tetrafluoroethylene) and poly(4-methyl-1-pentene) appear, respectively, under poly(ethylene) and poly(1-pentene).

Included as part of the polymer name column is the molecular weight of the chemical repeat unit of the chain, that is, of the constitutional base unit. This is given in parentheses just below the polymer name. The values reported are in grams per mole.

Unless otherwise indicated, the reference cited in the last column applies to all of the data in that line of the tables. Where an entry in a line has been taken from a source different from that listed in the reference column, a *solidus* (/) separates the value of the entry from the reference citation. For example, one value of the melting point of poly(1-butene) is given as "126/12" which is to be read as "126°C according to Ref. 12".

The crystal system, where known, is given in column 2 of the table, using the abbreviations given later. The next column contains the space group symbol (the Schoenflies notation is used because of the limitations of common printers at mainframe installations) with the subscript portion of the symbol preceding the superscript portion. Thus, according to Ref. 14, the poly(ethylene) unit cell is orthorhombic (Ortho) with space group D_{2h}^{16} (D2h-16). For a fuller discussion of space group symbols, see "International Tables for X-Ray Crystallography", Vol. I, Kynoch Press, Birmingham, England, 1952.

The dimensions of the unit cell (*a*, *b*, *c*) are given next, in Angstroms (1 Å = 0.1 nm). *c* is the fiber axis. Unless otherwise indicated, the unit cell angles are all 90°. Where only one angle differs from 90°, its value is given. When all three angles differ from 90°, their values are listed in the order α, β, γ. The next column contains the number of constitutional base units in the unit cell described.

Columns 9 and 10 contain the densities of the completely crystalline and of the completely amorphous polymer, respectively. The values given, normally appro-

References page VI-159

priate to room temperature, are in grams per cubic centimeter ($1\ g/cm^3 = 10^3\ kg/m^3$). For uniformity crystallographic densities (column 9) have been recalculated on the basis of the 1969 IUPAC atomic weight values. Melting points in degrees Celsius and heats of fusion in kilojoules per mole are listed in the next two columns. The heats of fusion correspond to the amount of substance represented by the molecular weight associated with each polymer name.

Column 13 of the tables indicate briefly the conformation of the polymer chain in the crystal (in a helical notation) either as reported in the reference cited or as inferred from the value of the fiber axis. The designation $n * p/q$ specifies the number (n) of skeletal atoms in the asymmetric unit of the chain and the number of such asymmetric units (p) per q turns of the helix in the crystallographic repeat. Thus, poly(ethylene), as listed, has two carbon atoms in the backbone with one such unit per turn in the repeat – it is designated as a $2 * 1/1$ helix. Alternatively, poly(ethylene) considered a poly(methylene) would be designated as a $1 * 2/1$ helix – an entirely equivalent description of the conformation. Note that n may differ from the number of chain atoms in the constitutional base unit. On the one hand, isotactic poly(propene) has two skeletal atoms in the asymmetric unit and three units per turn ($2 * 3/1$). On the other hand, syndiotactic poly(propene) with the same constitutional base unit as isotactic poly(propene) has four skeletal atoms in the asymmetric unit and two units per turn ($4 * 2/1$). In this case, n signifies the number of skeletal atoms in the stereobase unit. A fuller discussion of this helical notation is given in Hughes and Lauer, J. Chem. Phys., **30**, 1165 (1959) and in Nagai and Kobayashi, J. Chem. Phys., **36**, 1268 (1961).

This list of polymers and data is not considered to be exhaustive. The compiler expands it as new information is unearthed and he is quite receptive to notification of omissions and/or corrections and to submission of unpublished data. All of the data in this table cannot be considered to have the same validity – the number of polymers for which detailed, accurate, and reliable crystal structure analyses have been conducted is still quite limited. The reader may find it desirable to refer to the original literature cited so as to gain a fuller appreciation of the reasons for apparent discrepancies within the tables.

The following abbrevaitions have been used in the tables.

Tri	Triclinic
Mono	Monoclinic
Ortho	Orthorhombic
Tet	Tetragonal
Rho	Rhombohedral (trigonal)
Hex	Hexagonal
P	Pseudo
Phex	Pseudohexagonal

C. MELTING POINTS OF POLYMERS

In the following table of melting points, entries are alphabetical according to the basic structure of the polymer, ignoring substituents. Substituted polymers are listed alphabetically (according to the substituent) under the entry for the unsubstituted polymer. The molecular weight is that of the chemical repeat (the constitutional base unit) in the polymer. Melting points (in °C) are taken from the reference cited. Melting points are presented in this table only for those polymers without (as yet) available crystallographic data: an asterisk (*) in the reference column signifies that the relevant melting point data is contained within the "Crystallographic Data" table of Section B.

D. APPENDIX: FORMULA INDEX TO THE TABLES

As the number of crystallizable polymers and their complexity increased, it became necessary to devise a simple, reasonably unambiguous scheme to relate polymer structure to the specific name given to that polymer.

Some time ago, the compiler designed a shorthand notation to represent the structure of linear polymers which has proved to be useful. This scheme requires one to write the line formula for the constitutional base unit (without concern for priority or direction rules) and to count the groups/atoms comprising the unit in a specified order. In a sense, this scheme is analogous to the Chemical Abstracts Formula Index, but emphasizes groups commonly occuring in linear organic polymers rather than atoms exclusively. This scheme has the additional advantage of ensuring that data for a given polymer are not entered in the tables under differing polymer names.

The rules of this scheme are simple – count the number of groups/atoms in the constitutional base unit in the following order:

1. $-CH_2-$ (methylene as such, but not the $-CH_2-$ portion of a $-CH_3$ group).
2. $-CO-$ (carbonyls).
3. $-C_6H_4-$ (disubstituted benzenes; phenylenes; monosubstituted benzenes with the fifth proton counted under point 5 below).
4. Carbon atoms not already counted (as in $-CH_3$, $-CH=$, $-C_6H_3=$, etc.).
5. Protons ($-H$) not already counted (as in $-CH_3$, $-NH-$, etc.).
6. Oxygen atoms (exclusive of those in carbonyls).
7. Nitrogen atoms.
8. Sulfur atoms.
9. Other atoms (F, Cl, Br, Si, etc.).

The string of nine integers thus generated, arranged in the above order, is the required structure code. By looking up this code in the Formula Index Table one can find the name under which the polymer in question appears in the data tables or, alternatively, by its absence, that no data has been found for the polymer in question. The Formula Index Table is arranged in ascending order of the structural code in columns 2–10 with the assigned polymer name in column 1. Note that some very long, complicated names have been truncated. This should cause little difficulty in the use of this table. Examples of the application of this scheme are shown below.

Experience has shown that this scheme generates unique codes for the vast majority of linear polymers capable of crystallizing. Where two or more polymers do have the same structural code, the choice of correct name is usually obvious from the structure. Of course, certain classes of polymers do tend to generate many members all having a single code – for example, all of the condensation poly(amides) having a given total number of methylene groups and differing only in the proportioning of these between the diol and diacid constituents. Again, no ambiguities arise.

An advantage of this structural coding scheme is its adaptability to electronic data processing equipment. The logical step beyond this scheme could be a strict sequential notation detailing each group and its position (similar to the ACS–IUPAC Nomenclature Recommendation) in a short-hand notation for conciseness and for computer compatibility.

D. APPENDIX: FORMULA INDEX TO THE TABLES

As the number of crystallizable polymers and their complexity increased, it became necessary to devise a simple, reasonably unambiguous scheme to relate polymer structure to the specific name given to that polymer.

Some time ago, the compiler designed a shorthand notation to represent the structure of linear polymers which has proved to be useful. This scheme requires one to write the line formula for the constitutional base unit (without concern for priority or direction rules) and to count the groups/atoms comprising the unit in a specified order. In a sense, this scheme is analogous to the Chemical Abstracts Formula Index, but emphasizes groups commonly occuring in linear organic polymers rather than atoms exclusively. This scheme has the additional advantage of ensuring that data for a given polymer are not entered in the tables under differing polymer names.

The rules of this scheme are simple – count the number of groups/atoms in the constitutional base unit in the following order:

1. $-CH_2-$ (methylene as such, but not the $-CH_2-$ portion of a $-CH_3$ group).
2. $-CO-$ (carbonyls).
3. $-C_6H_4-$ (disubstituted benzenes; phenylenes; mono-substituted benzenes with the fifth proton counted under point 5 below).
4. Carbon atoms not already counted (as in $-CH_3$, $-CH=$, $-C_6H_3=$, etc.).
5. Protons ($-H$) not already counted (as in $-CH_3$, $-NH-$, etc.).
6. Oxygen atoms (exclusive of those in carbonyls).
7. Nitrogen atoms.
8. Sulfur atoms.
9. Other atoms (F, Cl, Br, Si, etc.).

The string of nine integers thus generated, arranged in the above order, is the required structure code. By looking up this code in the Formula Index Table one can find the name under which the polymer in question appears in the data tables or, alternatively, by its absence, that no data has been found for the polymer in question. The Formula Index Table is arranged in ascending order of the structural code in columns 2–10 with the assigned polymer name in column 1. Note that some very long, complicated names have been truncated. This should cause little difficulty in the use of this table. Examples of the application of this scheme are shown below.

Experience has shown that this scheme generates unique codes for the vast majority of linear polymers capable of crystallizing. Where two or more polymers do have the same structural code, the choice of correct name is usually obvious from the structure. Of course, certain classes of polymers do tend to generate many members all having a single code – for example, all of the condensation poly(amides) having a given total number of methylene groups and differing only in the proportioning of these between the diol and diacid constituents. Again, no ambiguities arise.

An advantage of this structural coding scheme is its adaptability to electronic data processing equipment. The logical step beyond this scheme could be a strict sequential notation detailing each group and its position (similar to the ACS–IUPAC Nomenclature Recommendation) in a short-hand notation for conciseness and for computer compatibility.

Examples*

	Structure	
		Poly(styrene)
	1.0.1.1.1.0.0.0.1	Poly(*p*-fluorostyrene)
	1.0.0.7.4.0.0.0.2	Poly(3,5-difluorostyrene)
$—NH—(CH_2)_3—CO—$	5.1.0.0.1.0.1.0.0	Poly(6-aminocaproic acid)

In the first example, there is one methylene, one phenylene, one carbon atom not otherwise counted (in –CH=), and two protons not otherwise counted (one in –CH= and one in $–C_6H_4H–$). In the second example, the fluorine atom replaces a proton from the substituted benzene ring – no other change in code occurs. In the third example, the trisubstituted benzene ring is removed from category 3 ($–C_6H_4–$) and is placed in category 4 (carbon atoms not otherwise counted) as 6 carbon atoms and in category 5 (protons) as 3 protons. In the last example, there are five methylene groups, one carbonyl, no other carbons, one proton (from –NH–), no uncounted oxygens, and one nitrogen. The approximately 2700 entries in the Formula Index Table were generated in a similar fashion.

A. INTRODUCTION

Amorphous (noncrystalline) polymeric solids are either glasses or rubbers. A glassy polymer lacks long range order, and is below the temperature at which molecular motions take place on the time scale of the experiment. A rubbery polymer is above the temperature at which molecular motions take place on the time scale of the experiment. The glass transition temperature, T_g, is the critical temperature that separates glassy behavior from rubbery behavior. Many amorphous solids, including polymers, organic liquids, biomaterials, some metals and alloys, and inorganic oxide glasses, exhibit glass transition temperatures.

The dramatic change in the local movement of polymer chains at T_g leads to large changes in a host of physical properties. These properties include density, specific heat, mechanical modulus, mechanical energy absorption, dielectric coefficients, acoustical properties, viscosity, and the rate of gas or liquid diffusion through the polymer, to name a few. Any of these properties can be used, at least in a crude manner, to determine T_g.

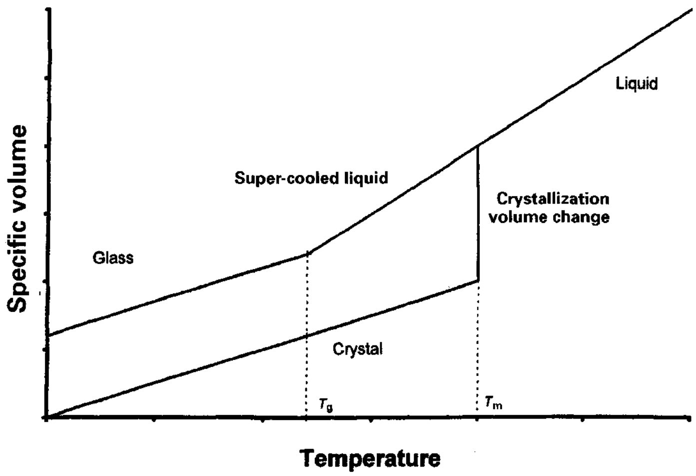

Figure 1.

1. Example of a Property Change at T_g

A classic method for determining T_g is dilatometry, in which the specific volume of the polymer is measured as a function of temperature. Figure 1 compares the specific volume vs. temperature curves for two idealized samples: a 100% amorphous material and a 100% crystalline material. Both materials follow the same path as their liquids are cooled from the melt. At the melting temperature, T_m, the crystallizing material orders into its crystal habit and exhibits a discontinuous decrease in specific volume. Below T_m, this solid has a reduction in specific volume with decreasing temperature, but the slope of this line, the volumetric thermal expansion coefficient, is less than the slope of the liquid line.

The amorphous material does not crystallize as the temperature falls below T_m, but continues to contract with a thermal expansion coefficient similar to the molten liquid: it acts as a supercooled liquid. At T_g, large-scale molecular motion (often considered to be the movement of 20–50 carbon atoms along a chain) becomes greatly reduced, the chain segments no longer rearrange rapidly in experimental time, and further cooling does not result in a similar volume change. Below T_g, the thermal expansion coefficient is similar to that of the crystalline solid. T_g can be defined as the temperature at the intersection of the two line segments. The specific volume is not discontinuous at T_g, as would be the case for the melting point, but the slope dV/dT, is. Therefore, T_g is sometimes referred to as a second-order transition, as compared to the melting point, which is a first-order transition. Both the primary property, specific volume, and its differential, the volumetric thermal expansion coefficient, change at T_g and can be used to identify the event.

Most polymer samples are either completely amorphous or partially crystalline. Figure 2 shows the specific volume vs. temperature curve for a semicrystalline polymer. The crystallizable fraction becomes ordered as it cools to T_m. Below the melting point, the amorphous material continues to contract as though it were a subcooled liquid, while the crystalline portion has a smaller thermal

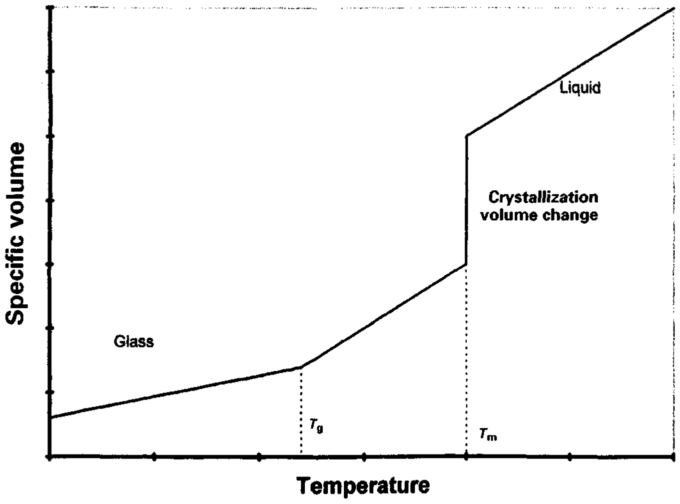

Figure 2.

expansion coefficient and contributes less to the volumetric decrease. Rapid amorphous phase motion stops at the glass transition temperature, and both solid components have similar thermal expansion coefficients below this temperature.

2. T_g: A "Non-Equilibrium" Transition

The glass transition temperature is not a fundamental thermodynamic property like the melting point because it is not thermodynamically stable, it is not defined by state variables, and its measurement is highly dependent on the time scale of the experiment used to determine its value. For example, experiments in which temperature or a deforming force is changed rapidly give higher T_g values than experiments in which conditions are changed slowly. Sample age and history affect the measurements as well.

The thermodynamic transition issue has been studied by a number of researchers. Staverman (1210) and Breuer and Rehage (1211) have concluded that T_g is not a true second-order transition because the glassy state is not completely defined by the normal state variables, p, V and T. Ehrenfest (1212) derived the following relationship that should hold for a true second-order transition:

$$\frac{dT_g}{dp} = \frac{T_g V(T_g)\Delta\alpha}{\Delta C_p} = \frac{\Delta\kappa}{\Delta\alpha}$$

where T_g is the glass transition temperature, p is the pressure, $V(T_g)$ is the molar volume at T_g, $\Delta\alpha$ is the thermal expansion coefficient difference (rubber to glass) at T_g, ΔC_p is the molar heat capacity difference, and $\Delta\kappa$ is the compressibility difference. Available data for a number of polymer systems show large deviations from the above equation for well-studied polymers, including polystyrene (1211), poly(isobutylene), poly(vinyl acetate), poly(vinyl chloride) and poly(methyl methacrylate) (1213,1214). The glass transition temperature is thought to be a kinetically controlled phenomenon (1215–1218).

B. T_g MEASUREMENT METHODS

The classical method of mercury dilatometer requires moderate amounts of sample, and time to permit thermal equilibrium to be achieved. Instruments that are easier to use and require only milligram quantities of sample are the thermal mechanical analyzer (TMA), the dynamic mechanical analyzer (DMA), and the differential scanning calorimeter (DSC). A TMA deforms a sample under a static load as the temperature is changed. At very low loads, it measures the specific volume change of the sample. A DMA measures the response of the material to an oscillating deformation. A DSC measures the change in sample enthalpy with time, dH/dt, for a known temperature program, dT/dt. The ratio of these two quantities gives dH/dT (also the specific heat capacity), which is a derivative measurement for T_g. (Experimental heat capacity curves of amorphous and semicrystalline polymers are given in the Heat Capacity chapter of this Handbook.) DSC is the most commonly used method for measuring the glass transition temperature of non-crosslinked polymers. All of these instruments can be interfaced to computers for data acquisition, test control, data reduction, and analysis.

The interpretation of T_g data can be controversial (1069–1071). The rate at which the sample is cooled or heated will affect the result. If the specific volume experiment of Fig. 2 was repeated for various cooling rates, T_g would occur at lower temperatures as the cooling rate is lowered, the transition region would become sharper, and a denser polymer would be produced. When a sample is allowed to remain below its glass transition temperature over a long period of time (aging), its density will increase. This process is called annealing; the rate of densification increases with annealing temperature.

1. Data Interpretation

The previous history of a sample will affect the measurement of T_g, unless the material's "memory" is erased by heating it well above the transition. The sample is heated well above its expected T_g, cooled to the original temperature, and reheated along a temperature profile to find the glass transition temperature of the material with minimal history. Some information can be inferred from the first heat, including residual stresses in the material, the presence of low-boiling diluents, etc.

The process of heating a polymer solid to find T_g often gives a curve similar to Fig. 1 and will produce a melt with the same density as that of the cooling experiment. However, in heating experiments, chain motions dominate the change in properties, and sudden property changes can occur near the transition temperature. At temperatures much higher than T_g, the property response once again becomes linear with temperature. In DSC measurements, sudden expansions can lead to an endothermic peak past the T_g. This endothermic peak has also been called enthalpy overshoot, and is thought to relate to the difference between the rate of temperature increase and the rate of increase of

chain mobility around T_g. The size of this overshoot depends on the annealing of the sample and the heating rate.

In a direct property measurement experiment (Fig. 1 is an example), it is common practice to ignore the kinetic effects of the transition region and to define T_g as the intersection of the two straight lines. For this case, the same T_g is found both on heating and cooling at a given polymer density. In an experiment that measures the differential of a property (DSC for example), integrating the curve gives the change in enthalpy from before to after the transition region, to which the simple intersection method of Fig. 1 can be applied, giving a T_g that is independent of heating rate (1079–1081). This method is well-known with inorganic glasses.

In DSC experiments, T_g is usually determined either by the onset point, the intersection of the initial straight line and the transition region straight line, or by the midpoint of the transition region (inflection point). The integration method's T_g is the same as the midpoint T_g if there is no endotherm, and is closer to the onset T_g if there is an endotherm. Moreover, it is common to measure T_g upon heating without any mention of previous thermal history or the heating rate. Because of these practices, the T_g values reported in this article should be considered as approximate by the reader. Authors reporting T_g should describe the thermal history of their measurements and also consider the integration method of determining T_g.

The classical methods of T_g measurement discussed previously can be quite insensitive for some polymers, e.g., highly crosslinked polymers. A penetration probe, on the other hand, is very sensitive and can determine T_g even on a thin film. But this method depends on the force of the penetrator and does not measure T_g in a fundamental way. Softening temperature methods are popular and are part of various ASTM standards.

2. Oscillating Load Methods

The measurement of the material response to an oscillating load gives a direct measure of the sample's modulus. The measurement of the lag of the material response (phase shift) to the mechanical forcing function gives a measure of the damping, or loss factor, of the sample. This last quantity is called the tan δ peak value. Dielectric thermal analysis is done by using an oscillating electric field as the forcing function. At T_g, there is often an order of magnitude change in the modulus and a large maximum in tan δ. This α-transition is distinguished from other thermal transitions (β, γ, etc.) by being the most dominant and occurring at the highest temperature. An onset point, a midpoint, or a change in modulus by a certain amount have all been used to mark the glass transition temperature. The tan δ maximum clearly specifies a thermal transition. However, it is necessary to independently determine that it is a glass transition and not another of the many transitions that appear in oscillating deformation methods. A classical T_g measured at a low programmed temperature rate (1 deg/min) may correspond to a tan δ measurement at a low frequency of measurement (1 Hz). The "loading rate" of a DMA experiment is the oscillating frequency, and T_g increases with frequency (analogous to the increase in T_g with heating rate in a DSC experiment). It is possible to measure a tan δ maximum at constant temperature while the frequency is being scanned and there is an inverse relationship between temperature and frequency. Even at a reasonably low frequency (10 Hz), a tan δ T_g can easily be 20–30°C greater than a classical one.

C. OTHER FACTORS AFFECTING T_g

Though the factors that govern T_g have been known for some years, there is still a wide variation in values for particular polymers. Polymer T_g's are sensitive to parameters which may or may not have been evaluated by the authors. Published values should be reviewed considering all the factors which affect T_g. The main factors affecting T_g values are polymer structure, sample crystallinity, diluent types and concentrations, molecular weight distributions, previous thermal history of the sample, and system pressure. More detailed treatments are given in reviews (6,48,49,1241–1249).

1. Structure

Within families of similar polymers, increasing chain stiffness and interchain cohesion increase the glass transition temperature. Copolymers may have one or multiple T_g's, depending on the ordering of monomers along the chain. The glass transition temperatures of copolymers may be higher, lower, or in between those of the homopolymers of their comonomers.

Most polymer structures are idealized and presumed from the characteristics of the reactants rather than proven by chemical and structural analysis. Structural uncertainties can arise both from the multiplicity of chemical reactions occurring during polymerization (especially those taken to high conversions), downstream processing, and from the structure of the reactants themselves. For example, a polymer with an asymmetric in-chain tetravalent atom can produce several stereoregular forms.

Alternatively, a polymer containing a residual double bond in the repeating unit could be in a *cis*, or *trans* conformation. Polymers of 1,3-dienes can have various combinations of *cis*, *trans*, 1,2- or 1,4-structures. Variations in these structural features can greatly effect the T_g values. Despite these uncertainties, the data are often useful if they can be regarded as pertaining to a polymer with reproducible properties.

2. Crystallinity/Crosslinking

Some workers suggest that the presence of crystallinity does not appreciably affect T_g. However, steric constraints imposed by crystalline regions on neighbouring amorphous polymer segments might result in an increase in T_g because

of the reduced mobility of these segments. In samples with crystallinity and moderate fractions of high molecular weight chains, tie molecules (long chains that have segments in more than one crystallite) provide physical crosslinking and increase T_g.

Some polymer families, such as the methacrylates and α-chloroacrylates, show high dependencies of T_g on tacticity. Intermolecular bonding can affect T_g either by increasing the cohesive energy of chain segments, or by decreasing the backbone degrees of freedom of chain segments. This last concept has been used (1240) to aid group contribution models.

As crystallinity increases, polymer T_g's may be little affected (50), may increase (51,52) (at least for isothermal crystallization (53)) or may decrease (51,54). T_g values selected in this work are the highest quoted on the sample with the lowest degree of crystallinity, other factors being equal.

In general, the presence of crosslinks in a sample increases its T_g relative to an uncrosslinked sample. This effect can be independent of the chemical composition of the crosslinking agent, caused by the restricted motion of chain segments near crosslinking sites. However, the crosslinking agent can behave similarly to a second monomer, inducing either an increase or a decrease in T_g due to the copolymer effect.

3. Diluents

Much of the variation in published T_g data is caused by the use of impure samples. Common impurities are unpolymerized monomer, low molecular weight polymer, solvents, and water. Great care should be taken to remove such impurities. Their presence in small concentrations can lead to a shift (48,98–103) in T_g of over 40°C and sometimes the occurrence of "diluent transitions", for example "water peaks". Preferred values are from publications that describe the precautions taken to exclude diluents and the residual levels of these diluents. Few references contain this information and most values should be regarded as only provisional.

4. Molecular Weight

The T_g of a homopolymer generally increases with increasing molecular weight up to a limiting value, known as the limiting or persistent T_g value (48,104,105). The reverse may hold for polymers with particular end-groups (106), or where crystallinity decreases with increasing molecular weight (107). For some polymers, T_g's are independent of molecular weight (108).

Many data, especially on condensation polymers, are for polymers of rather low molecular weight and it seems likely that higher T_g values would be obtained if higher molecular weight samples were tested. Many polymers are not properly characterized with respect to molecular weight and few have reported molecular weight distributions. In many cases, the only measure of molecular weight is a viscosity value, which itself can be very dependent on solvent–polymer interactions and, to some extent on the temperature. Usually, the highest viscosities and the highest molecular weight polymers are associated with the most reliable data.

The classical model for the effect of molecular weight on T_g is (1219–1226)

$$T_g = T_g^{\infty} - \frac{A}{\bar{M}_n}$$

This model suggests that the glass transition temperature reaches a limiting value when the number average molecular weight of the polymer is large. Cowie and Toporowski (1220) have shown that there is no further increase in T_g when the molecular weight is above a critical value, which is similar to the critical molecular weight for viscosity.

5. Thermal History

We have previously discussed in detail how thermal history (cooling rate, annealing time, and temperature), as well as the method of T_g measurement affects the reported T_g.

6. Pressure

Increasing pressure increases T_g in a linear relationship. A simple model is (Refs. 1227–1230)

$$T_g(p) = T_g(0) + sp$$

where $T_g(p)$ is the glass transition temperature as a function of pressure, p is pressure, and s is the linear pressure coefficient. This coefficient is 0.2 K/MPa for flexible aliphatic chains, and 0.55 K/MPa for semirigid aromatic chains (1231–1233). The effect of pressure on T_g can be important in some processing applications, such as injection molding. A different method for modeling the effect of temperature takes into account *pVT* data near T_g (1235–1237), giving an equation that includes the bulk modulus of the polymer glass.

D. ESTIMATION METHODS FOR THE GLASS TRANSITION TEMPERATURE

Several researchers have developed group contribution methods for correlating polymer properties, including the glass transition temperature (1238–1240). These techniques emphasize quantitative modeling of the various effects of polymer structure on T_g, and are a valuable aid to interpreting experimental data and estimating glass transition temperatures for new materials.

E. CLASSIFICATION, NOMENCLATURE, AND ABBREVIATIONS

Over 10000 papers contain glass transition data (43). This section of *Polymer Handbook* represents a fraction of these

data. Most of the data in the tables are for linear homopolymers. In general, the polymers contain no additives or diluents, and are thought to have low or no branching.

Polymers are subdivided into principle classes by the composition of their repeating chain segment: acyclic carbon polymers, carbocyclic polymers, acyclic heteroatom polymers, heterocyclic polymers, and copolymers. All entries are placed in the most senior class their structure commands (109,110) and appear in only one class. The subclasses and their entries are organized in alphabetical order.

1. Naming Conventions

With the exception of common polymers with accepted trivial names, the polymers are named substantially according to the ACS recommendations for polymer nomenclature (110) in conjunction with IUPAC rules (109); less common polymers are cross-referenced from the trivial to the systematic name. Systematic names are not given for all the polymers in order to save space. Substitutive nomenclature is generally used for simple radicals, but for long combinations of radicals replacement nomenclature has been used to provide a much shorter name (as for some fluorocrylates with ether side chains).

When sequences of radicals have repeated, the repeating sequence has been written once and prefixed "di", "tri", etc. as appropriate, for example, di(oxyethylene) for the sequence $-O-CH_2-CH_2-O-CH_2-CH_2-$. Note that the diradical "di(oxyethylene)" must be distinguished from the diradical "dioxyethylene" which has the structure, $-O-O-CH_2-CH_2-$, and also the diradical "ethylenedioxy" which has the structure, $-O-CH_2-CH_2-O-$ (IUPAC rule C205.2). The principle underlying the last-named diradical has not generally been extended to the naming of polymers in this section, *i.e.*, diradicals of structure –X–Y –X– are not named YdiX, with the exception of alkanedioyl diradicals, because of the difficulty of locating indexed polymer names in which the diradicals are not named from left to right. Many polymers are derivatives of the diradical "propylene" $-CH(CH_3)-CH_2-$; the substituted diradical "propylene" is used in naming polymers instead of "1-methylethylene" which could be preferred.

Polymer names are tabulated in alphabetical order within each subsection, but

1. prefixes like *sec*-, *tert*-, including designated atoms and the numbers showing locations of substituents are ignored except as secondary and tertiary indicators of order. For example, poly(ethylene 2,6-naphthalate) appears before poly(ethylene 1,4-terephthalate); poly(4-*p*-anisoylstyrene) appears before poly(4-benzoylstyrene).
2. multiplying prefixes for various substituents, such as dimethyl or trimethyl, are observed in alphabetical ordering rather than being grouped together as in the 3rd edition of this Handbook.
3. the locations of substituents in otherwise identical polymers are taken as tertiary indicators of order: the numbers are arranged in increasing order at the first point of difference. Thus, 2,3,8- comes before 2,4,1-.

Comments may include information as to the instrument of measurement and, whenever possible, information regarding the method of DSC measurement (e.g., onset), conditions of measurement, thermal history, and whether measurements were made as a function of a particular variable such as molecular weight (*f*(MW)).

Poly(phenylhydroquinone)		430		1312
4.31. POLY(QUINOXALINES)				
Poly(3-phenylquinoxaline-2,6-diylcarbonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		583	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diylcarbonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		595	Values range from 531 to 651 K	119,134,135
Poly(3-phenylquinoxaline-2,7-diylcarbonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene-1,3-dioxoisoindoline-2,5-diylcarbonyl-1,3-dioxoisoindoline-5,2-diyl-1,4-phenylene)		528	Dynamic method, heating rate: 5 K/min	111
Poly(3-phenylquinoxaline-2,7-diylcarbonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		516, 544	Conflicting data	119,134
Poly(3-phenylquinoxaline-2,6-diyloxy-3-phenylquinoxaline-6,2-diyl-4,4′-biphenylene)		683	Dynamic method	136
Poly(3-phenylquinoxaline-2,6-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		565	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		526, 543	Conflicting data possibly arising from different rate effects	119,134,137
Poly(3-phenylquinoxaline-2,7-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		571	Dynamic method	119,134,137–139
Poly(3-phenylquinoxaline-2,7-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenylene-1,3-dioxoisoindoline-2,5-diylcarbonyl-1,3-dioxoisoindoline-5,2-diyl-1,4-phenylene)		527	Dynamic method	111
Poly(3-phenylquinoxaline-2,6-diyloxy-3-phenylquinoxaline-6,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		710	Dynamic method	136

TABLE 4. *cont'd*

Polymer	CAS No.	T_g (K)	Remarks	Refs.
Poly(3-phenylquinoxaline-2,6-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		516	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diyloxy-3-phenylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		541		119,134,137
Poly(3-phenylquinoxaline-2,6-diyl-3-phenylquinoxaline-6,2-diyl-4,4′-biphenylylene)		677	Dynamic method	136
Poly(3-phenylquinoxaline-2,6-diyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		639–698	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diyl-3-phenylquinoxaline-7,2-diyl-1,3-phenylene)		593	Dynamic method	134,137
Poly(3-phenylquinoxaline-2,7-diyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		590–638	Conflicting data; dilatometric T_g 638 K	119,134,139
Poly(3-phenylquinoxaline-2,7-diyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene-1,3-dioxoisoindoline-2,5-diylcarbonyl-1,3-dioxoisoindoline-5,2-diyl-1,4-phenylene)		533	Dynamic method, heating rate: 5 K/min	111
Poly(3-phenylquinoxaline-2,6-diyl-3-phenylquinoxaline-6,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		567	Values range from 558 to 693 K	119,134,136,140
Poly(3-phenylquinoxaline-2,6-diyl-3-phenylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		558	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diyl-3-phenylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		561, 533	Conflicting data	119,134
Poly(3-phenylquinoxaline-2,6-diylsulfonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		543	Dynamic method	133
Poly(3-phenylquinoxaline-2,7-diylsulfonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene)		485–618	Conflicting data	119,134,135
Poly(3-phenylquinoxaline-2,7-diylsulfonyl-3-phenylquinoxaline-7,2-diyl-1,4-phenylene-1,3-dioxoisoindoline-2,5-diylcarbonyl-1,3-dioxoisiondoline-5,2-diyl-1,4-phenylene)		513	Dynamic method, heating rate: 5 K/min	111
Poly(3-phenylquinoxaline-2,7-diylsulfonyl-3-phenylquinoxaline-7,2-diyl-1,4-pheyleneoxy-1,4-phenylene)		468, 563	Conflicting data	119,134
Poly(quinoxaline-2,7-diylcarbonylquinoxaline-7,2-diyl-1,4-phenylene)		591	Heating rate: 20 K/min	119
Poly(quinoxaline-2,6-diyloxyquinoxaline-6,2-diyl-4,4′-biphenylene)		663	Dynamic method	136
Poly(quinoxaline-2,7-diyloxyquinoxaline-7,2-diyl-1,4-phenylene)		579	Heating rate: 20 K/min	119
Poly(quinoxaline-2,6-diyloxyquinoxaline-6,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		655	Dynamic method	136
Poly(quinoxaline-2,6-diyloxyquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		543		137
Poly(quinoxaline-2,6-diylquinoxaline-6,2-diyl--4-4′-biphenylylene)		659	Dynamic method	136,141
Poly[quinoxaline-2,6-diylquinoxaline-6,2-diyl-di(1,4-phenyleneoxy)-1,4-phenylene]		468	Dynamic method	141
Poly[quinoxaline-2,7-diylquinoxaline-7,2-diyl-di(1,4-phenyleneoxy)-1,4-phenylene]		508	Heating rate: 20 K/min	119
Poly(quinoxaline-2,6-diylquinoxaline-6,2-diyl-1,4-phenylene)		623	Dynamic method	141
Poly(quinoxaline-2,7-diylquinoxaline-7,2-diyl-1,4-phenylene)		649	Heating rate: 20 K/min	119
Poly(quinoxaline-2,6-diylquinoxaline-6,2-diyl-1,4-phenyleneoxy-4,4′-biphenylyleneoxy-1,4-phenylene)		486	Dynamic method	141
Poly(quinoxaline-2,6-diylquinoxaline-6,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		661, 553	Dynamic method, conflicting data	136,137,141
Poly(quinoxaline-2,7-diylquinoxaline-7,2-diyl-1,4-phenyleneoxy-1,4-phenylene)		580		119
Poly(quinoxaline-2,7-diylquinoxaline-7,2-diyl-*p*-terphenyl-4,4′-ylene)		578	Heating rate: 20 K/min	119
Poly[quinoxaline-2,6-diylquinoxaline-6,2-diyl-tri-(1,4-phenyleneoxy)-1,4-phenylene]		406	Dynamic method	141
Poly[quinoxaline-2,7-diylquinoxaline-7,2-diyl-tri-(1,4-phenyleneoxy)-1,4-phenylene]		489	Heating rate: 20 K/min	119
Poly(quinoxaline-2,7-diylsulfonylquinoxaline-7,2-diyl-1,4-phenylene)		615	Heating rate: 20 K/min	119

TABLE 4. *cont'd*

Polymer	CAS No.	T_g (K)	Remarks	Refs.
4.32. POLY(TRIAZINES)				
Poly(heptafluoropropyl-1,3,5-triazinediyltrimethylene)		253–255	No measurement details	155
Poly[(4-H-octafluorobutyl)-1,3,5-triazinediyltrimethylene]		253–255	No measurement details	155
Poly(pentafluoroethyl-1,3,5-triazinediyltrimethylene)		253–255	No measurement details	155
Poly[perfluoro(propyl-1,3,5-triazinediylhexamethylene)]		261	DTA heating rate	156
Poly(6-phenyl-1,3,5-triazinediylphenylimino-1,3,5-triazinediylphenylimino)		541–552	DTA heating rate	114
Poly(6-phenyl-1,2,4-triazine-5,3-diyl-2,6-pyridinediyl-6-phenyl-1,2,4-triazine-3,5-diyl-1,4-phenylene)		533	Dynamic method; different structural isomers may be present	157
Poly(6-phenyl-1,2,4-triazine-5,3-diyl-2,6-pyridinediyl-6-phenyl-1,2,4-triazine-3,5-diyl-1,4-phenylenemethylene-1,4-phenylene)		478	Dynamic method; different structural isomers may be present	157
Poly(6-phenyl-1,2,4-triazine-5,3-diyl-2,6-pyridinediyl-6-phenyl-1,2,4-triazine-3,5-diyl-1,4-phenyleneoxy-1,4-phenylene)		488	Dynamic method; different structural isomers may be present	157,158
Poly(2-H-tetrafluoroethyl-1,3,5-triazinediyltrimethylene)		253–255	No measurement details	155
Poly(1,2,4-triazine-5,3-diyl-2,6-pyridinediyl-1,2,4-triazine-3,6-diyl-1,4-phenyleneoxy-1,4-phenylene)		496	Heating rate: 20 K/min	159
4.33. POLY(TRIAZOLES)				
Poly(4-phenyl-1,2,4-triazolediyl-1,3-phenyleneimino-terephthaloylimino-1,3-phenylene)		623	DTA heating rate	173
Poly(4-phenyl-1,2,4-triazolediyl-1,3-phenylene-4-phenyl-1,2,4-triazolediyl-1,4-phenylene)		538		174

TABLE 5. COPOLYMERS

Polymer	CAS No.	T_g (K)	Remarks	Refs.
Copolyester (*p*-hydroxybenzoic acid-isophthalic acid-hydroquinone) 40 : 30 : 30		398–414		1436
Copolyester, aromatic		403–433		1509
Copolyester, aromatic		377		1269
Poly(alkylene *p,p'*-bibenzoate-b-tetramethylene ether)		205		1485
Poly(aryl ether sulfone-*b*-aryl ether ketone)		>473		1425
Poly(*t*-butyl methacrylate-*co*-styrene-*co*-butadiene-*co*-styrene-*co*-*t*-butyl methacrylate)		423		1377
Poly(ε-caprolactone-b-1,5-dioxepen-2-one-β-ε-caprolactone)		235		1515
Poly(carbonate-*co*-butylene terephthalate) 0.5/0.5		363		1386
Poly(3-carboxyphenyl maleimide-*co*-styrene)		493		1273
Poly(4-carboxyphenyl maleimide-*co*-styrene)		493		1273
Poly(2-chloro-1,3-butadiene-*co*-ethyl methacrylate)		238		1360
Poly(2-chloro-1,3-butadiene-*co*-glycidyl methacrylate)		257		1360
Poly(chloroprene-*co*-ethyl methacrylate)		238		1543,1360
Poly(chloroprene-*co*-glycidyl methacrylate)		256		1543,1360
Poly(chloroprene-g-ethyl methacrylate)		230		1360
Poly(chloroprene-g-glycidyl methacrylate)		243		1360
Poly(*N*-cyclohexylmaleimide-*alt*-isobutene)		465		1465
Poly(ethylene oxide-b-dimethyl siloxane-b-ethylene oxide)		156		1500
Poly(ethylene oxide-*co*-epychloridrine)		233		1415
Poly(ethylene terephthalate-*co*-*p*-hydroxybenzoic acid)		333		1517
Poly(ethylene-*co*-methacrylate)	25103-74-6	237		1307
Poly(ethylene-*co*-methacrylic acid) ionomer	25053-53-6	330	DSC	1265
Poly(ethyl methacryate-*co*-methyl methacrylate, 40 : 60)		377		1552
Poly(ethyl methacrylate-*co*-methyl methacrylate, 30 : 70)		365		1552
Poly(furfuryl acrylate-*alt*-2-hydroxyethyl methacrylate) 50 : 50		326		1279
Poly(3-hydroxybutyrate-*co*-4-hydroxybutyrate)-18		269	NMR	1494
Poly(3-hydroxybutyrate-*co*-4-hydroxybutyrate)-69		237	NMR	1494
Poly(β-hydroxybutyrate-*co*-hydroxyvalerate)		257		1560

A. INTRODUCTION

1. Background

1.1. General Remarks This chapter is intended to serve as a useful compendium of crystallization data for many types of polymers and polymeric systems. Some information is also provided on the fundamentals of crystallization (nucleation and growth) of these materials, with appropriate references relating to the techniques that are usually employed to study phase transformation processes in polymers. Controversial issues on growth and morphology will be mentioned briefly so that the reader who is new to this field will gain some perspective on the theoretical and experimental developments that have evolved over many decades, although this has little bearing on the numerical data presented here. This presentation serves not only as a guide to the data, but as a timely attempt to alert the vigilant reader to some difficulties, and some intricacies and problems of polymer crystallization that may be encountered in the literature (1–5).

The third edition of this Handbook reported the rates of crystallization for homopolymers (1–5), polymer blends (6,7), and copolymers (8). This edition updates this information, adds polymeric mesophases, and factors other than temperature that effect crystallization behavior. Within the past decade, crystallization of polymer blends have become increasingly important industrially. Besides the property-synergism provided through blending, there is a further economical incentive to use available materials rather than attempt to develop new polymers. Solid-state multiphase systems provide challenging academic research problems because polymer compatibility, *per se,* dominates morphology, whatever the crystallinity content of the system. The phase transformation depends upon the polymer type, monomer size and placement of the monomer units comprising the macromolecules (10). Sequence length and blockiness often feature strongly in determining rates of crystallization and levels of crystallinity. Related monotonic changes sometimes occur in physical parameters such as melting points and glass temperatures, crystallinities, and heats of fusion (11). The usefulness of a material depends upon the magnitude of these parameter changes. Polymer blending can often provide dispersions with overall properties that are superior to those of the respective components in the system, whether they crystallize or not. Blended mixtures frequently phase separate, but others maintain their morphological and physical integrity in practical applications (12). Cocrystallization may occur sometimes if there is lattice matching of the crystallographic chain axis repeat dimension and direction, and packing in the lateral directions within the crystallites is not too disruptive. In these circumstances the property changes may be striking. A fundamental knowledge of the kinetics of crystallization helps one to modify and improve properties (15).

The crystallization and morphology of lyotropic and thermotropic phases have only been developed comparatively recently, though liquid crystal polymers were recognized experimentally (13) and theoretically (14) a long time ago. The guidelines established for small-molecule liquid crystals (15) have been helpful for macromolecules, but they too may be misleading at times, particularly for polydisperse high-molecular-weight polymeric mesophases (16) and where their structural features are submicroscopic. Kinetic information for liquid crystal polymer systems is growing but still sparse (17,18). Synchrotron radiation sources and rapid monitoring techniques (19,20) are now available nationally and internationally for measuring isothermal and nonisothermal changes (21) and these simplify the monitoring of *in situ* transformations. Spectroscopic procedures (22) are now more capable than ever for sensing and tracking rapid and specific motions that have escaped detection by conventional means until the present. In addition to high intensity X-ray and light (laser) sources (23), deuterium NMR methods (24) are being used and developed for studying molecular dynamics, structural, or orientational changes (25). These new classes of nondestructive experiments are essential for improving our understanding of polymer behavior in the condensed state.

1.2. Background Over the years, two parallel themes describing aspects of crystallization of synthetic polymers have been developed. The oldest of these (26,27,30) uses a thermodynamic approach and provides a statistical description of morphology related to polymer crystallization, morphology, and properties. The other approach (28–29) is about half a century old and prefers a kinetic description of the development of lamellar structures that are basic to nucleation, growth, and stability in this context. Each has its merits and shortcomings but neither model is a panacea. Now, there is a consensus over the molecular dimensions that characterize macromolecules in the condensed state (4), but controversy remains over the intricacies of crystallization and its role in determining structure–property relationships. However, with new techniques now available for surface investigations and data processing, the time may not be too far away for an atomic view of matter in real space. For information on this topic, the reader should consult the current literature (15,31).

Whenever a polymer melt (liquid) or solution is sufficiently cooled, it may spontaneously crystallize. For instance, a supersaturated dilute solution produces tiny single[1] crystals (32). Spherulites are formed from concentrated polymer solutions, and these most frequently grow from the supercooled molten state. These growth patterns only occur from "privileged" nuclei, i.e., those that are capable of growing with a decrease in free energy (i.e., enhanced stability) to form ordered structures. If the supercooled melt (liquid) does not undergo this discontinuous transformation, then it is destined to form a glass, a disordered condensed phase. The crystalline texture and

[1] More appropriately described here as solution-grown crystals.

morphology, as well as degree of crystallinity, depends to some degree upon experimental conditions (33,34). "Single" crystals are comprised of thin lamellae with diverse habits. These morphological forms are discussed later in this article. Lamellae are basic crystal structures, although their intricate morphology is still open to debate (15,16). The next steps in the hierarchical level of structure are many different kinds of spherulites that are polycrystalline. The exact morphology of these moieties is still unsettled though they were discovered about a century ago. Several factors may be involved, namely: (a) monomeric chemical repeat unit, (b) crystallization temperature, (c) molecular weight and molecular weight distribution, (d) degree of branching and crosslinking, (e) tacticity, (f) degree of supersaturation, and (g) environmental factors (stereochemical defects, stress, solvent, impurities, etc.) and so on. These items are not placed in order of importance. Morphology is often dictated by other circumstances. Merely by changing the concentration of polymer in solution or its solvent, it is often possible to cover the "morphological spectrum" of crystalline polymeric forms, ranging from the monocrystal (formed in very dilute solution) to spherulites (formed in relatively concentrated solutions or from the polymer melt) under quiescent conditions. Other external factors such as pressure or stress and orientation can also alter the morphology (5).

This article deals mainly with isothermal crystallization conditions, but kinetic results obtained under constrained conditions are also listed. These are in the minority but the literature is growing. Although nonisothermal transformations (35) dominate in industrial operations, the data are frequently proprietary and often peculiar to specific process conditions. For example, molding processes (36) and fiber extrusion (37) operations create complex crystallization patterns, but the literature and even patents are still sparse on kinetic details. Most manufacturing procedures actually originated in industry. Still, some aspects of the topic have been examined theoretically (38).

Again, the influences of nucleants or additives on crystallization behavior have made considerable inroads in the scientific and patent[2] literature (39), but the importance of shear rates (40,41) on crystallization kinetics is beginning to receive more attention in the literature (42). In the field of "single crystal" growth many new results have been added to older kinetic data (43,44) tabulated in previous editions of "Polymer Handbook". The most recent are concerned with the crystallization of oligomers of polyethylene, polyethylene oxide and so on. Many aspects of crystallization are reported in some recent reviews (45,45a,45b) and later in this article.

1.3. Morphological Outline/Growth Features Under quiescent conditions, most often in very dilute solutions, and in self-seeding procedures, crystalline lamellae or "single" crystals are formed. They are seldom more than 85% crystalline even for annealed samples. Within these crystals, the chain macromolecules are disposed with their chain axis (*c* axis) more or less perpendicular to the flat faces of the thin lamellar crystals. However, angles of inclination as large as 48° have been reported in polyamides (5). Lamellar thickness (45–48) is controlled by nucleation/growth conditions. Electron microscopy (48) and other studies (49) have shown that crystallization (growth) proceeds outward from a primary center (a nucleation site) until growth is arrested or slowed to an imperceptible level at very low supersaturations. Screw dislocations (50) that often grow perpendicular to the basal plane of the crystal have an unusually large Burger's vector (equivalent to the lamellar thickness). Growth rates perpendicular on the basal plane of the crystal have not been reported, but a knowledge of this process should provide a better understanding of morphology and mechanistic relationships in high polymers and copolymers as they interrelate to each other and determine properties.

Crystallization from more concentrated solution(s) or from the supercooled molten state produces spherulites that seem to have nucleated similarly, and the high supersaturations encountered lead to polycrystalline spherical arrays. These arrays are comprised of radiating platelets or lamellae (often splayed and branched) in which the polymer chains are also folded to varying degrees, dependent upon polymer molecular weight and experimental conditions. The chains are usually oriented tangentially to their growth direction. Because of this morphology, most spherulites show a negative birefringence since the polarizability along the molecular chain axis is much greater than it is transverse to it, except in polymers with highly polar side groups or in hydrogen bonded polyamides. A variety of textural/optical features are associated with changes in crystallite orientation. The literature (51,52,5a) is replete with details of spherulite morphology, but no unique growth mechanism has been reported. Indeed, one might question its uniqueness in materials science! It is appropriate to mention that many classes of other materials also form spherulites; see for example, sulfur (53) selenium (54), antimony (55), proteins and carbohydrates (56), graphite (57), silicates (58), and inorganic (59) and polar and nonpolar low-molecular-weight organic molecules (60), to cite some examples. Spherulites are almost ubiquitous given suitable growth conditions and their forms are diverse, but it is important to realize that other morphological forms exist.

Polygonized structures are produced when spherulites impinge upon each other, limiting further outward radial growth. Growth rate is extremely temperature-sensitive and it is nucleation-controlled but this has been questioned recently (61). Even so, it is generally agreed that polymer transformations from solutions and melts are nucleation controlled. There has been confusion sometimes over the terms used to describe (a) primary and (b) secondary processes. Nucleation is termed primary for the onset of crystallization; the propagation of lamellae/spherulites (*i.e.*, growth) is named secondary crystallization. Crystallization

[2] Patents are excluded from this article.

that occurs after the radial growth ceases, *i.e.*, "filling-in" or densification behavior in spherulites, is sometimes termed secondary crystallization. However, kineticists often restrict the term primary crystallization to the nucleation step (creation) of the phase transformation process, and secondary is given to that stage in the transformation where significant deviations from Avrami[3] kinetics may take place. Several *in situ* experiments have been made with synchrotron radiation to monitor intricacies of nucleation and growth with time using WAXS and SAXS modes (62). During the secondary stage, densification takes place (63) and improvements in crystallinity have been reported by dilatometry (64). Even so, it must be recognized that the density and perfection of a spherulite decreases as it grows outwards from its center. Changes in crystallite thickness that may occur with annealing are another matter that is still unsettled.

The temperature dependencies of spherulitic and crystal growth rate have been claimed to correspond closely (65) under comparable conditions of undercooling, but there are results to the contrary. In monodisperse poly(oxyethylene) (66) and poly(ethylene)s (67,68), the rate of growth of single crystals in the melt depends on the crystal thickness, determined primarily by the undercooling temperature. Chain ends have been reported to reside sometimes inside (67) but more often outside (68, 68a) the crystalline core of low-molecular-weight poly(ethylene)s below 400 CH_2's per molecule[4].

2. General Principles and Techniques Involved in Crystallization Rate Studies

2.1. Kinetics of Bulk Transformations Whenever a polymer crystallizes, the extent of the phase transformation depends upon the crystallizing species and the experimental conditions. High molecular weight polymers do not crystallize completely (9,69) because of topological constraints that lower crystallinity considerably. The classical isothermal transformation kinetics, initially formulated by Kolmogorov (70) and Göler et al. (71) were extended later by the Avrami theory that was initially formulated for metals and later modified, for example, by Evans (72) and others, for polymers. The Avrami (73) equation

$$\theta = \exp(-kt^n) \qquad \text{(A1)}$$

relates the fraction or amount of uncrystallized material that remains after time t, during an isothermal transformation to its growth rate parameter, k, and nucleation parameter, n. As formulated by Avrami, crystallization was presumed to take place under isovolume conditions.[5] Modifications have been made to equation (A1) to correct for incomplete crystallization (74). The mode of nucleation, n, is an integer that varies from 1 to 4, reflecting the geometry and dimensionality of the growth process, under ideal conditions. The different forms are summarized in the following table.

AVRAMI EXPONENT AND MORPHOLOGY

Exponent	Nucleation Type	Crystallite Shape	
1	Instantaneous	Rod	Constant
2	Instantaneous Homogeneous	Discoid/ Rod	Constant
3	Instantaneous Homogeneous	Sphere/ Discoid	Constant
4	Homogeneous	Sphere	Constant

There are also classical growth conditions where the diffusion limited rate proceeds as $t^{1/2}$ and n exhibits 1/2, $1\frac{1}{2}$ and $2\frac{1}{2}$ values. These examples have been addressed in detail in other texts (31). Still, it is worthwhile pointing out that other terminology has been used to describe the mode of nucleation. For example, $n = 3$ may be termed sporadic or predetermined in time where the form of growth is disklike (2D) or spherulitic, respectively. Anyhow, it happens that in polymer phase transformation the growth velocity proceeds linearly with time. Now that mesophase crystallization is receiving more attention (75), rod-like morphologies with $n = 1$ resemble those found in well-oriented fibrous homopolymer systems (76). Some non-integral values of n correspond to heterogeneous transformations for $n = 2$ and 3. Other values of n determined in kinetic experiments may arise from many factors connected with the morphological complexity of the polymeric system. Computer simulations (77–79) have been conducted to model the bulk phase transformation, but the analysis is seldom free of ambiguity for many reasons, except in the early stages of crystallization. Note that in a recent paper, Levine et al. (80) have pointed out that the Avrami–Kolmogorov isothermal growth equation should not be applied to nonisothermal transformations without proper concern for the microstructural features that are inherent in the sample itself. Again, they claim that measurements employing small samples are subject to error whenever anisotropicity features in this mean field theory. They obtained a modified equation from extensive computer simulations. Polymeric materials are likely to be subjected to these criticisms though they were mainly concerned with metallic and related systems. Polymers exhibit more serious side-effects[6] such as mixed types of nucleation (that causes more than one type of spherulite morphology), nucleation on impurities, severe volume shrinkage upon crystallization and variations in spherulite

[3] The basic concepts in this model are hardly commensurate with the known crystallization behavior of polymers; see for example, Ref. 5, p. 250.

[4] The most recent *in situ* synchrotron studies made with monodisperse *n*-alkanes ($C_{246}H_{494}$) have indicated that once folded chains have considerable ciliated disorder as formed at first, but they undergo a slower improvement in crystallinity as chains equilibrate (adjust) to twice folded lamellae of much higher crystallinity (68a).

[5] In polymer crystallization experiments this situation is never realized, but large single polymer crystals accompanied by small volume changes, have been produced in some solid state polymerizations. So far, kinetic measurements have not been made on these systems.

[6] These are intrinsic factors that are known to influence the Avrami exponent.

density (crystallinity) within and between the spherulite(s) all of which may contribute to nonintegral values of n. In view of these complexities, it is surprising that Avrami n values are taken seriously in practice, except for making comparative rate studies. It is even claimed (81) that the mechanical properties of spherulitic samples may be related to internal morphological defects, such as tie-molecules, and even voids created between confined spherulites during melt crystallization. Laser microbeam and X-ray microdiffraction has also been used to examine the internal morphology of spherulites (82,83). The kinetics of the embryonic nuclei and subsequent stages of spherulitic developments (84,85) from a sheaf-like morphology to a spherical entity (spherulite) have been studied using low-angle light scattering. Of course, electron microscopy (86,87) has recorded more detailed morphological changes at higher resolution, and atomic force microscopy (AFM) investigations have probed even further in this respect (88,89,89a).

In principle, any technique that can follow unambiguously the amorphous $\rightarrow$ crystalline transformation with time, under isothermal or non-isothermal conditions, can be employed as a bonafide method to detect and monitor the crystallization rate(s) that occur. Many experimental techniques exist, such as calorimetry (90), dilatometry (91), density balance (92) and density gradient (93), light depolarization (or transmission) technique (94,95) and/or small-angle light scattering (96) (for average spherulite growth rate measurements), infrared spectra (97), X-ray (98), nuclear magnetic resonance (99,102), electrical resistivity (100), and small-angle X-ray scattering (101), neutron scattering (103), atomic force microscopy (103a) and more. The Avrami θ may involve any property parameters, P_i's, that are relevant in the transformation time domain. In this respect, specific volume changes are related to θ by the equation

$$\theta = (v_\infty - v_t)/(v_\infty - v_a) \tag{A2}$$

Here v_a, v_t, and v_∞ correspond to the initial, intermediate, and final stages of the isothermal crystallization (71,104) and the other P_i's may be similarly incorporated. Wood and Bekkedahl (104) were the first to show that the overall isothermal transformation rate of rubber expressed as $(t_{1/2})^{-1}$ passes through a maximum as its crystallization temperature was lowered. It was later shown experimentally and theoretically that the spherulitic growth rate also proceeded similarly, as related by Eq. (A3). Simply expressed (105), k may be written as in Eq. (A1):

$$k = f(\dot{N}G^{\alpha}) \tag{A3}$$

where α is a geometric parameter that is three for spherulites, and it may take on other values for other geometrical shapes. Another formulation (106) obtained experimentally, at constant crystallization temperature, is

$$k = f[\dot{N}(MW,t)G^{\alpha}(MW,t)] \tag{A4}$$

since it was observed that nucleation rate, $\dot{N}$, and spherulitic growth rate, G, are each dependent on molecular weight, molecular weight distribution and time.[7]

The type of property, P, being monitored (107) depends upon the amorphous contribution, P_a, and crystalline portion, P_c, where each phase can be expressed as a weight fraction or a volume fraction in the simple two-phase model expressed as

$$P = xP_c + (1-x)P_a \tag{A5}$$

If P is specific volume then a weight fraction $x_c(w)$ is obtained, whereas a volume fraction $x_c(v)$ results whenever the sensing is made (for example) by X-ray or dilatometry. The relationship then becomes

$$\frac{1-x_c(w)}{x_c(w)} = \left(\frac{\rho_a}{\rho_c}\right)\frac{1-x_c(v)}{x_c(v)} \tag{A6}$$

where ρ_a and ρ_c represent the amorphous and crystalline densities, respectively. This model is an oversimplification (109) in that it does not allow for the increasing interdependence of the properties of each phase with changes in crystallinity. Other complications also arise because (i) crystallinity is molecular weight dependent (9,45,64) and (ii) for oriented systems, accurate determinations of crystallinity can be difficult (110,111). It strongly depends upon morphology.

Bulk crystallization rates are of some practical value in a relative sense (112) and depend markedly on the concentration of impurity nuclei (of adventitious origin or from additives or nucleants introduced deliberately for property or process control). No satisfactory way (other than counting primary nuclei, *i.e.*, spherulites) exists to quantify their concentration. Generally, spherulitic growth rate (after nucleation) is independent of how the spherulite originated (94,113) (*i.e.*, whether the nucleation is homogeneous, heterogeneous, or pseudo-homogeneous). On the other hand, it must also be recognized that bulk transformations can be greatly influenced by impurities.

Adequate fusion conditions and sample purification (94,114) must always be established for best results in a given system to suppress or eliminate adventitious heterogeneous nuclei in crystallization. Homogeneous nucleation is seldom encountered at small undercoolings (115); although it may be mimicked in the earlier stages of crystallization (116). Because of these complications, it is always advisable to combine complementary techniques; for example, optical microscope studies with dilatometric or other rate measurement. Reliable nucleation rates may only be deduced from independent measurements of

[7]On this account bulk rate measurements are intrinically controlled by two convoluted independent factors or parameters. Only a unique insight into interfacial growth mechanisms is obtained from spherulitic or lamellar ("single crystal-like") interfacial tranformations *per se* from the polymer melt or solution growth respectively, and not from a composite of G and N contained in (4) above.

References page VI - 391

(i) spherulitic growth rate and (ii) nucleation counts made over relatively long transformation times.

Investigations of liquid→solid phase transformations with SAXS and WAXS techniques now employ rotating anode X-ray (117) or the more intense synchrotron radiation sources for real time kinetic measurements. Normally, good policy to check samples for radiation damage after each experiment. Even so, it has been reported that the development of two or more crystal modifications may be identified and monitored *in situ* by synchrotron WAXS and SAXS investigations (118,119). Dilatometry, and/or DSC measurements for example, may be usefully combined with SAXS investigations where the absolute integrated scattering intensity Q was expressed (21) as

$$Q = K\phi(1-\phi)(\rho_c - \rho_a)^2 \qquad \text{(A7)}$$

and later modified to read:

$$Q = Kv_s\phi(1-\phi)(\rho_c - \rho_a)^2 \qquad \text{(A8)}$$

In this equation K is an instrumental constant, ρ_c and ρ_a being the densities of the crystalline and amorphous regions, respectively, ϕ is the volume fraction crystallinity, and v_s is the spherulitic volume. Note that Q increases with crystallinity, reaching a maximum around $\phi = 0.5$ as Sheldon had shown earlier. Rate profiles for poly(tetramethyl-*p*-silphenylene siloxane) [poly(TMPS)] fractions (21) of high and low molecular weights differ in some respects from measurements made by other techniques. Strangely, changes in Q for relatively long isothermal transformation times show no signs of the secondary crystallization often encountered in isothermal dilatometry for the same high molecular weight samples. Long period thickening becomes invariant with the time of crystallization in some polymers, but not in poly(ethylene) (25,117,121). Interestingly, synchrotron SAXS work on poly(β-hydroxybutyrate) (20) has shown that the long period is unaltered with time during isothermal crystallization from the melt even though crystals of this polymer have been found in another study (122) to thicken isothermally upon annealing. Elsewhere (123) in oriented poly(ethylene) the long periods are found to change reversibly between 30°C (217 Å) and 100°C (252 Å). Upon cooling of poly(TMPS) fractions, following isothermal crystallization, under quiescent conditions and reheating crystallized sample(s), a reversal of the long period,that is dependent upon molecular weight is observed (21). Concomitantly, the crystallinity increases upon cooling specimens from the crystallization temperature to room temperature (125). More detailed measurements have been made recently (62) where it was demonstrated that the increase in the degree of crystallinity by WAXS and SAXS cannot be correlated with the long period. Clearly, more investigations of this kind are needed.

2.2. Thermodynamic Crystallization Models Thermodynamic and statistical theories of morphology (124,126) *do not provide rate data* but only important crystalline/amorphous information, *i.e.*, morphological features consistent with thermodynamic quantities predicated to change with crystallization temperature or undercooling. Kinetically, these models hardly merit a place in this article on rate measurements except that they do provide information on the "equilibrium" crystallite size l_c in relation to its melting temperature T_m of the finite crystal, from the general expression of the form

$$\left(\frac{1}{T_m} - \frac{1}{T_m^0}\right) = \frac{R}{\Delta H_u}\left[\frac{2\sigma_e}{l_e R T_m} - \frac{1}{l_e}\ln\left(\frac{x_c - l_e + 1}{x_c}\right)\right] \qquad \text{(A9)}$$

that may be simplified for very long chains when the last term vanishes. In Eq. (A9), x_c is the molecular chain length, R, the gas constant, and ΔH_u, the ideal enthalpy of fusion per mole of repeat units comprising the crystallites of end interfacial energy, σ_e. $T_m^0 = \Delta H^0/\Delta S^0$ is the thermodynamic temperature of the infinite crystal with enthalpy and entropy, ΔH^0 and ΔS^0, respectively. Theories of melting of polymers have been the subject of much discussion (127) over the years. For example, the reported thermodynamic melting temperatures of poly(ethylene) range from 414 to 419 K and from poly(oxyethylene) from 342 to 348 K are in dispute based upon theory and experiment. At best, T_m^0 is only reasonably well established for a few well-characterized polymers, yet so much morphological, growth kinetics and structural interpretations are based upon T_m^0. Only a fraction ($\leq 70\%$) of the chains are folded into the end surfaces of the crystallite (126) but the quality and even the extent of the re-entry adjacency is still disputed.

The crystal fold surface of poly(ethylene) crystals and interfaces have been studied more than any other polymer (126–130). This dispute is likely to continue until the "crystal" surface morphology in real space (88,89) can be resolved and the corresponding surface(s) chemically analyzed by the newer experimental techniques of the last decade or more (131,132,133). It should be realized that the thermodynamic model, unlike the kinetic one, does not require a chain-folded nucleus, nor does it provide kinetic information.

2.3. Growth Kinetics of Lamellar Structures: Crystals and Spherulites Growth rate depends primarily upon the degree of undercooling rather than on the crystallization temperature, but the influence of chemical and physical structure and molecular weight and molecular weight distribution are also important factors in linear chain polymers. Without impurities, growth occurs isothermally at a constant rate, and the temperature dependence of these rates are typical of a nucleation controlled process (134), whatever the model employed to describe it.

Theories for isothermal growth rate-temperature, $G(T)$, in polymeric and other less complex systems can be formulated simply by

$$G(T) = f(T)D(T) \qquad \text{(A10)}$$

which is often approximated by

$$G(T) = \frac{f(T)}{\eta(T)} \tag{A11}$$

It is frequently assumed that the temperature dependence of the diffusive term $D(T)$ is reciprocally related via the Stokes–Einstein relationship[8] to the zero shear viscosity $\eta(T)$ which is more readily available than $D(T)$. The $f(T)$ term in equations (A10) or (A11) differentiates between the growth geometries introduced in various growth rate models. Different formalisms (1(a),4,15,61,119-121,134-137) invoking chain folding and diverse nucleus/growth geometries have been used to simulate crystallization. One of the most elaborate and widely used kinetic descriptions[9] is the modified multiparameter model of the original Hoffman–Lauritzen theory (1). Another salient model is that to Point (137), who first predicted the correct crystal thickness temperature up to large undercooling, that is accordance with experimental evidence (138–140). Point and others (137), have disputed some of the basic ideas in Hoffman's model, that pertain to a stable nucleus and to surface energy and other related features connected with growth Regimes that are now postulated to describe interface roughness and interfacial energy assigned to three stages of undercooling (see below in text). Point's test of Regime theory (141) questions its validity, though there is much experimental evidence (142) *pro and con* for "transitional breaks" in growth rate with undercooling. The matter is still unsettled.

The Hoffman–Lauritzen spherulitic growth rate equation (A1) is similar in principle to the Becker–Döring model (except for the complexions that are invoked to incorporate chain folding). The basic equation can be represented formally by

$$G = G_0 \exp\left(-\frac{\Delta E^*}{RT}\right) \exp\left(-\frac{\Delta G^*}{RT}\right) \tag{A12}$$

In which G_0 is a constant for a given molecular weight, ΔE^* is the activation barrier to molecular chain transport, and ΔG^* is the free energy barrier to nucleation.[10] However, the L–H model differs in several important macromolecular details that distinguish it from small molecule morphology. Following the *ad hoc* assumption that the first exponential in the crystallization equation (A12) may be approximated by a Vogel or modified[11] Williams–Landel–Ferry (WLF) type of term,[12], Eq. (A12) becomes

$$G = G_0 \exp\left[-\frac{A}{R(T - T_0)}\right] \exp\left[-\frac{\Delta G^*}{RT}\right] \tag{A13}$$

Here T_0 lies at least 30° below the glass transition temperature T_g, at a temperature where growth enabling motions vanish. A is an activation energy for such segmental transport, usually $\sim$5 kcal/mol. The nucleation term is often expressed as

$$\exp\left[-\frac{BT_m^0}{T\Delta T}\right] \tag{A14}$$

Here the undercooling $\Delta T = (T_m^0 - T)$ and T_m^0 is the melting temperature of the perfect polymer crystal, most often obtained by extrapolation. The term ΔT^{-1} implies two-dimensional surface nucleation (growth) but it has been claimed (143) that a ΔT^{-2} dependence provides an equally valid fit to experimental growth rate data. The geometric parameter B may be expressed as

$$B = nb_0\sigma\sigma_e/f\Delta h_f k \tag{A15}$$

where b_0 is the inter planar distance in the growth direction, σ and σ_e are the lateral and end surface (interfacial) free energy of the growing crystal or lamella[13], k is Boltzmann's constant, and Δh_f is the heat of fusion of the crystal. The adjustable parameter $f(0 \leq f \leq 1)$ accounts for the temperature dependence of the heat of fusion away from the melting point. Another fitting parameter ψ, $(0 \leq \psi \leq 1)$ is an "apportionment factor" of the bulk free energy associated with nucleation and growth away from the melting point. This has been troublesome in the past, amounting to serious discrepancies between theoretical and experimental values of lamellar thickness, l, with undercooling and it was referred to (by Hoffman et al.) as the "δl catastrophe" (1). Now, in a recent paper by Snyder et al., (146), claim to have resolved this problem. This integer n, (is not to be confused with the Avrami, n, in equation (1)). The Hoffman parameter, n, is both morphology and growth rate related and is claimed to coincide with nucleation Regime changes at the growth front with undercooling in some polymers

[8] Only valid for spherical molecules, but it has been used indiscriminately.

[9] Questions have been posed (61) that challenge the mechanistic nature of the nucleation processes *per se*. Recent AFM work has shown (68a) that growing polymer lamellae at the melt-crystal interface exhibited sporadic behavior with time, suggesting that stress may be a significant influence. Interestingly, reports on asymmetric aromatic hydrocarbons (60) have cited and demonstrated stress related growth behavior at faceted spherulitic interfaces. In this paper it was stated that this could complicate growth rate measurements unless proper care was exercised. The implications of this commonality in the behavior of polymers and small molecules may lead to further interesting investigations into materials, generally.

[10] Recently it was reported (144a) that the β-relaxation process is responsible for nucleation from the quenched state but this seems to be irrevalent to isothermal crystalliztion that takes place directly from the supercooled molten state well above the glass transition temperature. Crystallization from the supercooled melt and from glassy polymers (see Ref.5, p.258 and elsewhere) and small molecules were investigated (60) in some detail a long time ago and explained along conventional lines by the writer.

[11] The writer (60,144) pointed out decades ago that it differed in magnitude, from the macroscopic viscosity (or fluidity) temperature dependence by fitting experimental data for asymmetric aromatic hydrocarbons.

[12] Just recently (145), further considerations of Eq. (A13) concludes that a better "fit" to transport data is obtained by compromising the C_1 and C_2 parameters in the classical WLF type formulation for transport in the melt.

[13] This geometry is consistent with many polymer morphological habits.

(1,147,148). It alters for a smooth interface ($n = 1$) to a rough one ($n = 3$); $n = 2$ corresponds to an intermediate morphology. Several "transitions" in growth rates (149–152) are claimed to be consistent with Hoffman's predictions. Before this theory, "breaks" in the growth rate with undercooling were assigned to morphological changes, but now it is accepted by many investigators though the entire issue is still under discussion.

The concept of reptation[14] (7,152(a)) is another process that has been claimed facilitate chain folding[15] of lamellae, and to circumvent chain entanglements at the melt-crystal interface during crystallization. Experimental evidence (see for example 30, 45,69,144,153–155) questions its validity in interfacial growth kinetics, *whenever spherulitic growth over a wide span of molecular weight fractions is investigated.* For example, the dependence of the interfacial surface energy of crystallites on molecular weight is contrary to expectations if reptation was indeed functional. Clearly, it does not override topological constraints and multiple nucleation events that suppress chain folding and seriously diminish sample crystallinity in poly(TMPS) and polyethylene - see for example (Ref. 155). It is well known that low molecular weight crystalline fractions are mostly chain folded and brittle because of the lack of tie-molecules. On the other hand high molecular weight fractions are tough due to the existence of disordered regions as well as the presence of tie molecules. Hikosaka (156) has proposed another kinetic model for crystallization that simultaneously deals with lateral lamellar growth (chain-folding) coupled with crystal thickening for extended chain growth. Hikosaka and co-workers (157) believe this theory accounts for pressure crystallized polymers (158) and chain extended polymeric mesophases (159). Now, an all-encompassing crystallization scenario involving both of these features is claimed to be relevant in all polymer transformation kinetics (157). Although interesting, this model is open to question because other investigations dealing with *in situ* real time monitoring of "solid" phase transformations (1162) points out that melting *per se* precedes chain extension.

Another model termed Molecular Nucleation has been emphasized by Cheng and Wunderlich (160a) as a significant factor in the crystallization of PEO fractions and mixtures but it is not readily amenable to experimental testing yet, although it has received favorable mention from Point (159a). *So far, all theories of polymer crystallization and morphological models formulated, do not have à priori predictive capability whether they invoke chain folding implicitly or not.* The formation of lamellar structures is amply backed by electron and X-ray diffraction evidence (4,47,160) but real surface details are still lacking. Studies of well-defined oligomers of poly (ethylene) (67,68) and poly(oxy-ethylene)'s (66) support chain folding in short-chain polymers crystallized from the melt, yet the latest WAXS and SAXS measurements indicate that there are conflicting details too (68a,160).At this stage, it appears that the evidence is insufficient to take a polarized stance on this problem bearing in mind the balance of existing evidence and not opinion.

[14] A recent review (45b) still insists on this process even though it is unable to facilitate chain folding in high molecular weight polymers, nor is it required to account for crystallization behavior below the entanglement molar mass, M_c.

[15] If folding is a consequence of kinetics, it is an inherent surface defect that compromises the attainment of high degrees of crystallinity even under the most favorable circumstances. Multiple nucleation and topological contraints worsens this flawed situation even more as physical measurements have shown (eg. see situation summary in Ref. 155). Another publication is in press.

3. Other Significant Aspects of Crystallization

In the preceding sections, some of the following items have been mentioned, but the writer believes that they deserve more attention as many of these areas have grown since the publication of the third edition of this Handbook. For example, there have been developments in:

(I) Non-isothermal crystallization
(II) Crystallization of blends
(III) Solvent and pressure induced crystallization
(IV) Mesophase crystallization
(V) Flow induced crystallization
(VI) Epitaxial crystallization
(VII) Orientational crystallization from the melts and solutions
(VIII) Crystallization of copolymers
(IX) Computer simulations

A brief foreword is given by way of introduction in these important areas. Rate measurements in all of these fields except for epitaxial crystallization appears in the tabulated data in this chapter. In some respect, the growth experienced on a given topic is connected with practical developments and manufacturing and that often provides the opportunities for further investigations.

3.1. Nonisothermal Crystallization This important aspect of polymer crystallization is responsible for the morphology and properties of processed polymers that are crystallizable (ie. polymers, blends, mesophases or any combination of these ingredients in a plastic product) to whatever extent. in the developments. There are many complex events responsible for polymer properties. Several approaches have been used to gain a better representation and understanding of non-isothermal crystallization processes, since the quality of manufactured plastics goods depends upon it. Processing induced structures are never homogeneous even when the materials are thin films or fibers. Because of their complexity, years ago fundamental knowledge was gained through experiments, but now computer modeling has increased in popularity. Several approaches to this problem exist. The techniques of Ozawa (162) Nakamura et al. (163) are still popular. In essence, they have been usually modeled as an extension of

Avrami theory

$$\theta(t) = \sum_{j=1}^{k} \theta_j(t) \qquad \text{(A16)}$$

where the phase change over the crystallization range is considered to be comprised of many incremental isothermal parts so that where $j = 1$ to k involves all the types of nuclei (i.e., homogeneous, heterogeneous, pseudo homogeneous, thermal, athermal and so on). The nucleation rates $\dot{N}(t)$ and growth rates $G(t)$ has been patterned as

$$\dot{N}(t) = \dot{N}[f(t)] \quad \text{and} \quad G(t) = G[f(t)] \qquad \text{(A17)}$$

Simplifying assumptions lead to a more general equation. After some manipulations, it becomes:

$$\log\{-\ln(1 - x(t)\} = \log k(T) - n \log \beta \qquad \text{(A18)}$$

where $x(t)$ is the fraction of material transformed at T and β is the cooling rate, $k(T)$ is the cooling rate function and n is the Avrami exponent. From plots of $\log\{-\ln[1 - x(t)]\}$ vs. $\log \beta$ a straight line is obtained if Osawa's method is valid. From this plot, $k(T)$ and n respectively can be obtained.

Harnisch and Muschik (164) derived the Avrami equation from non-isothermal crystallization thermograms where

$$x(t) = 1 - \exp(-k_n t^n) \qquad \text{(A19)}$$

A plot of $\log\{-ln[1 - x(t)]\}$ vs. $\log t$ for each cooling rate is linear, providing the adjustable parameter k_n and n that are needed. Two parameters are different from the isothermal values. Besides this, it is important to realize that the heat of fusion of the 100% crystalline polymer is needed for the data analysis.

Ziabicki (165) developed a procedure where he assumed that crystallization in polymers may be represented by first order kinetics, i.e.,

$$\frac{dx}{dt} = (1 - x)kT \qquad \text{(A20)}$$

wherein overlap of growing moieties is neglected and $k(T)$ is a temperature dependent rate constant. Plots of rate constant vs. T is Gaussian-like; so that the kinetic crystallizability C, may be expressed in terms of D, the width of the crystallization exotherm at half-height and k_{max} equals k at the top of the exotherm

$$C = \int_{T_g}^{T_m} k(T)dT = (\pi/\ln 2)^{1/2} k_{max} D/2 \qquad \text{(A21)}$$

Depending upon the polymer and its crystallizability (fast vs. slow kinetically), C varies more than three or more orders of magnitude (polymer to polymer) but kinetic parameters obtained from Ziabicki's method do not always compare well with other methods. Except for tests on blended systems in recent literature (164) others were reasonable. A generalized theory by Ziabicki (165), containing the thermodynamics and kinetics of phase transitions, while sound in concepts, appears complex and not readily amenable to testing.

Whenever polymer melts or solutions are sheared (166) the nucleation rate can often be drastically enhanced so that the overall transformation rate becomes accelerated, if the conditions are conducive to crystallization (167,168). If the external cooling is sufficiently rapid, the level of crystallinity may be compromised for instance in molded parts that may subsequently crystallize slowly (ie. age in storage) causing serious changes in dimensions that could cause distortion in the workpiece. Moisture conditioning of polyamides, for example, is a well practised industrial procedure that is used to stabilize fibers "on-line" and as processed molded parts. Network systems undergo non-isothermal crystallization or isothermal crystallization when they are oriented uniaxially (169) or biaxially (170). Some of them have been analyzed from the viewpoint of kinetics and/or thermodynamics as further alluded to in the next section. Non-isothermal crystallization at varying cooling rates is representative of actual polymer processing situations. Integral methods have been developed (171) for simulating the material fraction of transformed material under arbitrary cooling rates but the widespread use of Avrami theory has been criticized (see Computer Modeling section).

In industrial processes rapid sample cooling and monitoring has been a problem. Years ago, the writer introduced the light depolarization intensity method (LDI) to follow rapid changes taking place "on the spin line" and in laboratory tests (94). This procedure is now widely used and has just been further developed (95) to cope with average cooling rates as high as 5000°C/min. for the investigation of non isothermal crystallization generally (i.e., with constant and varying cooling rates) as Spruiell and coworkers have demonstrated for polyolefins. Over the years, Janeschitz-Kriegl and coworkers (see for example, (38)) have investigated the theoretical and experimental difficulties associated with transport and transformation processes encountered in polymer crystallization. In recent papers, they have detailed their findings.

3.2. Crystallization of Blends The first polymer blend was made from two polymeric rubbers in 1846, but polymer blend technology and a scientific understanding of the underlying principles controlling the compatibility (or lack of) in polymer mixtures (alloys as they have been named recently) has taken place only in the latter part of the current century. Many blends are non-crystalline but our interest in this document is focused on the kinetics of phase transformations of binary and ternary systems that receives more attention annually. Some of these systems can be very complicated, often comprised of multiple phases that may involve homopolymers, copolymers, mesophases and the like. Polymorphism and even isomorphism may occur

because of inherent chemical interactions, imposed temperature and pressure conditions and so on. Despite these complexities, blends comprise a significant part of industrial production where synergism among materials is often exploited through various processing techniques.

The lattice theory of Flory–Huggins captures the essential features of mixing and demixing and the magnitudes of their corresponding entropic and enthalpic changes have provided a basis of understanding for some fifty years ago (172). Since then, experimental practice and more subtle theoretical developments, including computer simulations, have advanced our understanding of homopolymer and copolymer blends (see for example, Binder (173)). With mesophases the situation becomes more complex but it is still beneficial in practical ways. On the technological side, Utracki (174,175) has provided informative overviews of the processing science and technology of blends or alloys in detailed accounts of processing-morphology-property relationships.

Crystallization always involves phase changes and often insufficient attention is given to transformation rates that may correlate strongly with structural and morphological details. For polymer mixtures/blends and copolymers with one or more random components, certain generalizations may be made when they are crystallizable. For instance in bulk crystallization, the Avrami or a related theory has often been employed to analyze bulk kinetics in blends to demonstrate the strong effect of molecular weight and composition on transformations rates. There is an analogy here with homopolymers in that crystallization rate is usually suppressed by the non-crystallizable component(s) in the system. Consequently transformation curves are moved to lower temperatures, although their transformation isothermals are seldom superposable (as they are in most homopolymer transformations). Spherulitic growth rates are usually attenuated too and shifted toward lower temperatures as the results compiled in this article show. The crystallization of blends has been modeled by thermodynamic or kinetic type equations employing computer simulations.

3.3. *Solvent and Pressure-Induced Crystallization* Diluent or solvent in a polymer system, alters its crystallizability and often its crystallinity is enhanced. Solvent-induced morphological changes (176) may occur and mechanical properties and deform ability including aging behavior (177) of systems can be affected so that the topic is of considerable importance technologically. Plasticizers (178), nucleants (179), and chain length (180) may attenuate or sometimes accelerate the phase transformation kinetics. Several types of investigations and analysis have been employed. Mandelkern and others have adopted a thermodynamic approach where the focus is on the overall Gibbs free energy for nucleus formation, while crystallization kinetics has been investigated by using the Avrami theory as a basis for detecting mechanistic changes with time, temperature, and diluent concentration. For spherulitic growth kinetics the effect of diluent on morphology and crystallization kinetics has been formulated (74) according to

$$G = G_0' \exp\left\{\frac{-A'}{R(T - T_0)}\right\} \exp\left(\frac{-\Delta G^* - \Delta G_s^*}{RT}\right) \quad \text{(A22)}$$

where ΔG_s^* is the free energy contribution from the solvent (diluent), the other terms having been defined before. Equation (A22) may be modified to take care of crystal geometry and polymer diluent interaction. These effects are very marked in many polymers, especially where plasticizers that modify physical behavior are involved, as for instance moisture in polyamides. In these circumstances the defining parameters A', G_0', T_0' are altered (usually decreased in magnitude compared with homopolymers). In non-compatible polymer blends (181) this is often a rare event, and changes in morphology and crystallization behavior have not always been documented even when rates have been measured. Copolymer systems are being studied more extensively (181), and spherulitic growth rates (181,182) are receiving some attention as later tabulated results illustrate.

Pressure induced crystallization has been documented for a few systems (183), poly(ethylenes) (31,46,184) in especially being the most extensively investigated materials from a morphological and properties viewpoint. Conformational constraints are responsible for gauche bond formation in polyethylene, for example, lead to the formation of the higher entropy hexagonal phase as a morphological high-pressure intermediary that is essential to the overall thermodynamic picture of its melting temperature-pressure phase diagram. Other kinetics data (185–190) are also listed in this article. Pressure is a significant processing parameter. In the past, experimentation was the "yard stick" rather than theory for optimization of polymer processing conditions. Crystallization kinetics made by dilatometry at small undercoolings (190a) has moved the focus to the process rather than on the product itself for nylon 66, polypropylene and poly(ethylene terephthalate). According to Zoller (190a), the Malkin modification of the Avrami equation best describes the kinetic data in this investigation. Other systems such as polypropylene behave likewise, and *PVT* modeling studies have been published (190b,190c).

3.4. *Crystallization of Mesophases* Although polymeric mesophases were discovered more than one century ago (191), their exploitation has only been developed within the recent decades. Synthesis, properties and applications have been the focus of most studies because of the technological potential of these systems. Now that it is known that mesophases form supermolecular structures through self-organization, this discovery has lead researchers to investigate the criteria underlying liquid crystalline formation. The morphology and structure of these polymers have been the subject of theories (14,192,193) and experiments (194). Molecular design *vis a vis* properties (somewhat analogous to activities in drug chemistry/

industry) has become an attractive research topic. The molecular requirements for liquid crystallinity have been featured in papers and reviews (195) that have also covered lyotropic and thermotropic phases. Structure in these types of phases have sometimes been tailored to ease processing and/or to facilitate or even to reduce rates of crystallization. Blending has been tackled through processing and modeling, including phase separation dynamics (196); yet crystallization kinetics, despite its importance, has had a low profile until comparatively recently, kinetic measurements on mesophases are still sparse. Most results known to the writer, are tabulated in this article. Rate data have been analyzed along the conventional lines normally used for homopolymers in Section B. Insufficient research has been devoted to the development of a new theory and to examine the influence of crystallization rate on morphology-processing-property relationships; viscosity and diffusion considerations notwithstanding.

Crystallization of some thermotropic copolymers cannot be explained on the Flory model (192) through homopolymer segregation. However, Windle and coworkers (197), by means of computer modeling have demonstrated that 3D ordered regions, described as non-periodic layers (NPL) are possible. Structurally, NPL crystallites agree with experimental X-ray observations even when random intramolecular statistical sequencing exists. This ongoing project is of interest as the NPL model may also be explained by a paracrystalline lattice (PCL) model, that does not require explicit sequence matching (198).

3.5. Flow-Induced Crystallization This topic covers polymer solutions and melts (199,200) generally and may be further categorized into

(a) flow induced Poiseuille flow (201),
(b) elongational flow (199),
(c) shear induced transformations (202,203),

and there are others.

Polymers, other than homopolymers (i.e., blends, copolymers, mesophases) have been listed according to processing characteristics. Rates of crystallization in these categories are sparse compared with synthesis, structure, morphology, properties, processing and even computer simulation (the latter being a rapidly growing field), with some information on the factors/forces that modify behavior. An exception is the work of McHugh and coworkers (204,205) who have reported the strain induced crystallization rates of swollen poly(ethylene) networks by using dynamometry coupled with *in situ* fiber video-imaging with birefringence measurements in order to obtain one dimensional heterogeneous growth rates. However, the deformation rates encountered in these experiments are much lower than the values encountered in commercial fiber melt spinning and molding processes.Still, modeling is now underway to link transient deformation histories with flow induced shear results (205). These authors have just developed a continuum model for flow induced crystallization that embodies strain induced crystallization by employing an irreversible thermodynamic formalism based upon principles set forth by Beris and Edwards (206) for describing non equilibrium irreversible thermodynamics of flowing systems.

The Hoffman has developed a kinetic model for fibrous crystal growth from solutions (207). It is patterned after the well established pioneering solution spinning "shish-kebab" textures, and properties by Pennings and coworkers (see for example 208,208a) and others (208b) especially for UHMWPE and their blends. In this model, "shish's" comprise a well-oriented central core fibrils ($\sim$15–50 nm) flanked by chain-folded "kebab" overgrowths off the core. The "shish" cores are interconnected by highly strained amorphous regions. They (core regions) contain many defects. Here again, the paucity of experimental rate data hampers testing of the theoretical model.

3.6. Epitaxial Crystallization This aspect of crystallization deserves to be mentioned. Polymer–polymer epitaxy (209–210) involving mutual interactions between different macromolecules where crystallinity, crystal structure, lattice matching, molecular conformation and chemistry have been considered. The kinetics of epitaxial processes have been largely ignored despite their plausible significance in surface bonding that has practical implications.

Recent experiments (211) have shown that the lamellar thickness of poly(ethylene), PE, on oriented isotactic poly(propylene), changes from 16 to 39 nm upon annealing. This thickening is attributed to dimensional matching and secondary nucleation with the requirement (212) that the PE crystal(s) are thinner than the ^{i}PP dimension along the chain-row matching direction. However, no detailed kinetic measurements were reported on the rate of epitaxial growth here, or elsewhere in the literature.

3.7. Orientational Crystallization Strain, shear, and elongational flow under isothermal or nonisothermal conditions promote crystallization. The problem is of long-standing commercial importance in fiber manufacturing, injection molding (213) and other important processes. On the academic side, the problem has been recognized for a long time, but it has been studied only sporadically until now (203). Although published data are still sparse, useful behavioral trends have been established.

Crystallization of *cis*-1,4-polybutadiene between rollers during shearing has been modeled (214) using a novel procedure in which the influences of shear flow on lateral heat conduction is approximately avoided. This technique permits the crystalline layer build-up to be determined as a function of time, temperature, and shear rates in on-line processing. The morphology created under these conditions was studied. This is not an easy "kinetic" problem to handle theoretically.

Crystallization in polymer networks has received some attention (169) since Flory proposed the basic principles many years ago (215). Gaylord (216) modified this theory

for finite chains while others studied and determined the interrelation between elongation, melting, and crystallinity. Calculated strain dependence of the melting temperatures (max), average crystallite sizes and crystallinity extension ratios, λ's, as high as four for crosslinked rubber networks have been correlated, but rates of crystallization were not included in this kind of work that is further addressed by Negahban in Section IX.

3.8. Crystallization of Copolymers In this category, the focus has been on morphology and properties though Flory (215) developed an equilibrium thermodynamic description of the semi crystalline state of these materials almost half a century ago. Fusion of copolymers is expected to occur over a wider range of temperature in contrast to homopolymers. Random and block copolymers have been studied and melting theories are widely used to describe them. Whenever one species of a copolymer is crystallizable and is dependent upon its sequence probability, p, and not on composition, its melting behavior has been described[16]. The technological importance of copolymers has developed over the years, but kinetic descriptions of the phase changes observed (often multiple) have been mostly patterned after models for blends that are analogously related to equation (A22) whenever crystallization proceeds according to a spherulitic morphology. The non-crystallizable component(s) affects crystallization parameters in accordance with their degree of compatibility and interfacial transport that often constrains and usually suppresses growth rate. Even so, the morphological features that determine the overall crystallization kinetics and properties do change with molecular weight and co-unit content and rates have been monitored and analyzed mostly according to procedures outlined in Section A. Morphology varies with molecular weight akin to the behavior encountered in homopolymers. Avrami type transformations and spherulitic growth rates tabulated in this article indicate that the time scale of the transformation is strongly influenced here (more so than it is in blends of the same composition) for species with similar compositions. Other copolymers behave similarly even though the range of molecular weights for these random copolymers of ethylene is not extensive (216,217). Other kinetic theories of copolymer crystallization have been formulated (218) and tested. Modeling of copolymers with short crystallizable sequences using a Monte Carlo approach (219) has been aimed to reveal the 3D morphology of A-B type crystallites such as ethylene-propylene with high propylene content and low crystallinity. This work shows promise. Goldbeck-Wood (220,221) has written an informative overview of computer simulations where the focus has been on molecular dynamics and Monte Carlo simulations pertaining to classical lamellar crystallization and 3D models. The reader should consult the original texts for details.

3.9. Computer Simulations On this topic, there have been a number of developments that have a kinetics basis, apparently connected with assumptions used in the Avrami theory that only provides analytic solutions. In simulations, the approach has been used to model bulk transformations for:

(a) volume shrinkage, non-random nucleation and crystallinity variability (222),
(b) spherulite impingement in two dimensions on SALS patterns (223),
(c) the morphology of spherulites (thermally and athermally nucleated) (224) and the implications of various nucleation modes, as well as density changes and size distribution effects,
(d) isothermal kinetics in thin films, including the influence of surface nucleation on morphology (225,226), and
(e) simulation of crystallization in polymeric composites in two dimensions with some representation of the three dimensional situation (227), and for several other criteria too.

Simulation of phase transformations in these examples have some predictive capability. For composite systems, the Avrami model as such, is claimed not to apply because nucleation is constrained by fiber loading and surface sites. For instance, factors such as fiber fraction and diameter, spherulitic growth (normal and transcrystalline) must all figure in the overall composite morphology.

Another different, but recent approach by Negahban and coworkers (228–230) to crystallization kinetics involves modeling:

(a) thermo-mechanical effects that occur during the phase transformation in "simple" homogeneous processes,
(b) simulation of the thermo-mechanical effects of crystallization in non-homogeneous processes and,
(c) developments of models for the prediction and verification of material responses.

There are other criticisms of the Avrami method here. Negahban points out that modeling of crystallization kinetics using Avrami-type equations "is incompatible with the entropy production inequality" (i.e., Clausius Duhem inequality) that is basic to the termination of crystallization in real situations. Much of his work has concentrated on the crystallization of rubber (literature results) with all its ancillary effects/property-wise material functions that are amenable to simulation. In the same manner, the kinetic theory of crystallization, based upon concepts of molecular chain-folding and it's related parameters,at the same time recognizing some of the shortcomings involved. An attempt has been made to keep

[16] Goldbeck-Wood [Polymer **33**, 778 (1992)] has developed a new melting point equation that is comparable with Eq. (A23) (see below) for copolymer melting point depression, but it predicts a much steeper dependence on composition than the Flory model which states

$$\frac{1}{T_m} - \frac{1}{T_m^0} = -\frac{R}{\Delta H_u} \ln p \qquad \text{(A23)}$$

where p is the sequence probalility [P. J. Flory, Trans. Farad Soc., **51**, 848 (1955)].

this section relevant to crystallization kinetics even though modeling/simulation procedures are becoming widely applied now, on account of growing availability of computers. In this regard one of the more recent practical computer simulations that has been developed for injection molding,embodies nonisothermal and stress–induced crystallization kinetics in poly(phenylenesulfide) during processing (232). The authors claim to be able to "predict" the thermomechanical history and crystallinity developments in PPS in reasonable agreement with experiment. Undoubtedly, there will be further developments in this field,because of its technological and economic relevance.

ADDENDUM

This chapter on "Rate of Crystallization of Polymers" is incomplete for several reasons. Sometimes original data were not available. Where the deconvolution of complex graphical kinetic scenarios was unnecessarily tedious and resulted in questionable accuracy, these data were omitted. However, results are listed for rate plots that could be deciphered and digitized satisfactorily. Original data provided directly by authors are included and gratefully acknowledged by the writer.
